Early approaches to OD centered primarily on the implementation of humanistic ideals at work. The types of values emphasized included personal development, interpersonal competency, participation, commitment, satisfaction, and work democracy (French & Bell, 1999; Mirvis, 1988). The focus generally was within the workplace.

Over time, however, there has been a shift in OD emphases. In comparison to its early formulations, OD now pays much more attention to the larger environment in which the business operates and aims at helping businesses accomplish their strategic objectives, in part through organizational alignment with the larger environment (e.g., Bunker & Alban, 2006; Holman, Devane, & Cady, 2007; Seo et al., 2004).

Early approaches placed considerable emphasis on individual and group development within the organization (e.g., Harrison, 1970), and, although the words “the whole organization” were used, the types of change fostered by OD often focused more on the group (e.g., team building) or other organizational subunits. Given the organizational environment of the 1980s and beyond, individual and group development became less emphasized unless they were treated within the context of large systems change and the adjustment of an organization to its larger environment. Such adjustment often involves radical departure from the organization’s prior strategic emphases (Nadler, Shaw, & Walton, 1995), and is sometimes referred to as organizational transformation (e.g., Nadler et al., 1995), or radical organizational culture change (e.g., Cameron & Quinn, 1999). In recent years, the roles of external stakeholders in major organizational change have been appreciated much more (Bunker & Alban, 2006).

Despite the shifts that have occurred in understanding of OD's focus, there remains an emphasis on OD as humanistically oriented, as concerned about the people who make up an organization, not just the strategic goals of the organization. Thus, for example, Church, Waclawski, and Seigel (1999) define organization development as the process of promoting positive humanistically oriented large-system change. By humanistic they mean that the change is "about improving the conditions of people's lives in organizations" (p. 53). Beer and Nohria (2000) include OD within the category of capacity building interventions in organizations, not as primarily economically oriented.

THE CONCEPTUAL KNOWLEDGE OF ORGANIZATION DEVELOPMENT

Contemporary as well as past approaches to OD are based on more or less explicit assumptions about (a) the processes through which organizations change and (b) the types of intervention approaches that lead to change. These two phrases, which seem quite similar, actually represent two different conceptual approaches, one that is more likely to be addressed by academic writing on OD and one that is more likely to be addressed by practitioner writing. Early approaches to action research likely treated these as congruent (e.g., Highhouse, 2002), but that has not been the case for several decades (Beyer & Trice, 1982). We will use them to frame approaches to change that are presented primarily for academics and primarily for practitioners.

In 1966, Bennis distinguished between *theories of change* and *theories of changing*. Theories of change attempt to answer the question of how and why change occurs. Theories of changing attempt to answer the question of how to generate change and guide it to a successful conclusion. Porras and Robertson (1987, p. 4) expanded on Bennis's notion, relabeling the two different approaches as *change process theory* and *implementation theory*. (Though the categories are essentially the same, we will use Porras and Robertson's terms, since they are much easier to distinguish.)

Porras and Robertson (1987, 1992) described change process theory as explaining the dynamics of the change process. This approach centers around the multiple types of variables involved in the accomplishment of planned change. In contrast, they described implementation theory as "theory that focuses on activities change agents must undertake in effecting organizational change"

(p. 4). They included strategy, procedure, and technique theories as examples of implementation approaches.

Porras and Robertson's focus was primarily on OD interventions as explicitly defined. As noted earlier, however, the understanding of dynamics of change has been widened well beyond OD (e.g., Van de Ven & Poole, 1995; Weick & Quinn, 1999). Porras and Robertson also asserted that change process theory should inform implementation theory; that is, the findings of academic research should inform practice. There is awareness now that OD practice should also have an impact on academic knowledge (Bartunek & Woodman, in press; Rynes, Bartunek, & Daft, 2001).

In this chapter, we expand on the understandings of change process theory and implementation theory. We will describe an array of change process theories, using the model developed by Van de Ven and Poole (1995) for that purpose. We will also describe several implementation models and suggest possible links between them and change process models.

We noted above that academic writing tends to focus more on change process theory while practitioner writing focuses more on implementation theory. There has been relatively little interaction between the two types of theories; to some extent they occupy separate intellectual spaces and are held in more or less separate "communities of practice" (J. S. Brown & Duguid, 1999; Corley & Gioia, 2011; Sandberg & Tsoukas, 2011; Tenkasi, 2000). Change process theories tend to draw from empirical work grounded in academic fields such as psychology, sociology, economics, and anthropology. Implementation theories tend to draw from practitioner-oriented experiential work; they may emerge from the same academic disciplines as change process theories, but do not make the connections explicit. Hopefully, this chapter will suggest useful connections between the two.

Change Process Theories

Porras and Robertson (1992) concluded their review of organizational change and development research with a call for increased attention to theory in change research. Through attention to the variety of ways organizations might change, scholars have answered this call.

Researchers have approached the task of understanding organizational change from a wide array of perspectives. In their interdisciplinary review of about 200 articles on change, Van de Ven and Poole (1995) identified four ideal types of change theories that encompass many of these perspectives. They labeled them as life-cycle, evolution, dialectic, and teleology, and located OD primarily within

the teleological framework. These four types are distinguished by their underlying generative mechanisms, or motors. Van de Ven and Poole suggest that most change (process) theories can be understood within one motor or a combination of motors.

We found evidence of extensive theory development pertinent to OD based on each change motor. Below we summarize change research categorized by primary underlying motor of change. With Van de Ven and Poole (1995), we recognize that most change theories capture elements from different motors, although one motor is typically primary.

The Teleologic Motor

The teleologic motor describes organizational change as the result of purposeful social construction by organization members. The motor of development is a cycle of goal formation, implementation, evaluation, and modification. Organizational change is goal-driven; impetus for change emerges when actors perceive that their current actions are not enabling them to attain their goals, and the focus is on processes that enable purposeful activity toward the goals. The teleologic motor can be found in most contemporary theories of organizational change. For example, recent extensions of evolutionary theories and institutional theories—evolutionary innovation and institutional agency—have adopted a teleologic motor. Change leadership theories rely on the teleologic motor as well. We summarize some teleologic change theories that have emerged or reemerged.

Strategic Change

Rajagopalan and Spreitzer (1996) observe that strategic change primarily deals with teleologic change. Underlying most strategic change theories is the understanding that planned change triggered by goal-oriented managers can trigger change in both an organization and its environment. Following this teleologic logic, several researchers have sought to understand the role of leadership in generating organizational change (Doz & Kosonen, 2010). Bass's transformational leadership framework (Bass & Avolio, 1994) posits that organizational change emerges as the result of leaders' attempts to develop their followers and transform follower goals to more closely match those of the organization. Other researchers view organizational change as the end result of cognitive development of organizational leaders (Hooijberg, Hunt, & Dodge, 1997; Torbert, 1991). Strategic change underlies most practitioner work in change management and is the place of intersection between the teleologic motor and change

management practice. Popular books on leading change have in common a central focus on strategic change (Heath & Heath, 2010; Kotter, 2008; Kotter & Cohen, 2002; Patterson, Grenny, Maxfield, McMillan, & Switzler, 2008).

Cognitive Framing Theories

Several studies emphasize the importance of cognitive change by managers in creating organizational change. Reconceptualization of the context then leads to further cognitive change in a continuing iterative process (Barr, Stimpert, & Huff, 1992; Bartunek et al., 1999; Levinthal & Rerup, 2006; Weick, 1995). Gioia and Chittipeddi (1991) found that managerial efforts to communicate a planned change built cognitive consensus, which further enabled the change. Issue reframing is another cognitive framing theory of change with growing interest. Change is enabled through the active framing and reframing of strategic issues by organization leaders (Doz & Kosonen, 2010; Sonenshein, 2009). Reframing has been of particular interest to researchers seeking to understand emergent innovation (Jansen, Vera, & Crossan, 2009) and has formed the basis for techniques designed to trigger creative strategic thinking (Day & Schoemaker, 2008; Kim & Mauborgne, 2004).

Theories of Innovation

Several researchers consider how individual attempts at innovation combine with environmental characteristics to generate organizational change (C. M. Ford, 1996; Glynn, 1996). Innovation emerges from an alignment of numerous actions and environmental factors such as social networks (Lee, 2007; Owen-Smith & Powell, 2004), information flows (Miller, Fern, & Cardinal, 2007; Soh, Mahmood, & Mitchell, 2004; Zaheer & Bell, 2005), climate and existing knowledge (Smith, Collins, & Clark, 2005), organizational design (Westerman, McFarlan, & Iansiti, 2006), and collaboration and alliances (Sampson, 2005, 2007). Glynn (1996) proposes a theoretical framework for how individual intelligence combines with organizational intelligence to generate creative ideas. These ideas are then implemented, provided certain enabling conditions (adequate resources and support, incentives and inducements) are present. This process presents a model of organizational change that is driven by individual cognitions and collective sensemaking processes within the organization. Types and directions of search activities also can drive innovation (Siggelkow & Rivkin, 2006) and influence the manner and content of the change. Amabile and her colleagues (Amabile, Conti, Coon, Lazenby, &

Herron, 1996) build from an individual level of creativity to identify group- and organization-level constraints on individual creativity and subsequent organization-level innovation.

Taken together, research on innovation and creativity reveals a complex mix of predictors of organizational change. At the center of these predictors is the teleologic assumption of goal-driven, purposeful action. As Orlikowski and Hofman (1997) note, the specific decisions and immediate strategies may be unplanned improvisations, but they are guided by a goal-driven theme. Recent theorizing on organizational innovation highlights the interaction between purposeful action, sensemaking, organizational settings, and environmental jolts to trigger organizational change (Ahuja, Lampert, & Tandon, 2008; Drazin, Glynn, & Kazanjian, 1999).

OD reflects many of these approaches. As noted earlier, there is much more emphasis now on OD accomplishing strategic ends (Jelinek & Litterer, 1988; Bartunek et al., 1999) and on the role of leadership in these processes (Nadler & Tushman, 1989). There has also been some attention paid to cognitive framing of different participants in a merger process (Marks & Mirvis, 2001). Such framing is one of the hoped-for outcomes of large-group interventions (Bunker & Alban, 2006; Holman et al., 2007).

The Life-Cycle Motor

The life-cycle motor treats change as a progression through a predetermined sequence of stages. The ordering of the stages does not change, but the speed of progress and the triggers that lead to advancement through the process vary. Van de Ven and Poole (1995) note that the “trajectory to the final end state is preconfigured and requires a specific historical sequence of events” (p. 515).

While life-cycle models of organizational change proliferated in the 1970s and 1980s (Quinn & Cameron, 1983), we found little continued theoretical development of this motor since 1995. One exception is in the area of entrepreneurship, where theorists continue to use a life-cycle motor to understand the creation, development, and failure of new ventures, including ventures that arise out of the death of prior ones (Alvarez & Barney, 2007; Hanks, Watson, Janson, & Chandler, 1994; Walsh & Bartunek, in press). Variations of the life-cycle model, especially in conjunction with the teleologic motor, are also apparent in research on punctuated equilibrium. It emerges as a motor in several OD approaches, discussed in the next section, such as transforming leadership (Torbert, 1989) and advanced change theory (Quinn, Spreitzer, & Brown, 2000).

Punctuated Equilibrium

The evolution–revolution framework of organizational change (Greiner, 1972) has formed the foundation of many organizational change theories (Mezias & Glynn, 1993) that have been used to describe dynamics in organizations. Greiner described the typical life cycle of an organization as consisting of extended evolutionary periods of incremental change interspersed with short revolutionary periods. This framework provides the basis for theories of strategic redirection (Doz & Prahalad, 1987), transformation (Laughlin, 1991), punctuated equilibrium (Tushman & Romanelli, 1985), and change archetypes (Greenwood & Hinings, 1993). During reorientations, large and important parts of the organization—strategy, structure, control systems, and sometimes basic beliefs and values—are expected to change almost simultaneously in a way that leads to very different organizational emphases.

Tushman and Romanelli (1985) suggested the effectiveness of punctuated equilibrium approaches to change, but others suggest some cautions in the use of this approach. Previously established competencies may be threatened by transformations (Amburgey, Kelly, & Barnett, 1993). In addition, Sastry (1997) found that reorientation processes increased the risk of organizational failure unless evaluation processes were suspended for a trial period after the reorientation. However, certain change processes may enable successful reorientations. Mezias and Glynn (1993), for example, suggest that previously established routines may guide reorientations in such a way that competencies are not destroyed.

There have also been questions raised about how frequent true reorientations of the type suggested by Tushman and Romanelli are. Cooper, Hinings, Greenwood, and Brown (1996) have suggested that, instead of true reorientations, the types of change that typically occur involve one layer of orientation placed on top of another layer that represents the prior orientation. Reger, Gustafson, DeMarie, and Mullane (1994) have also suggested that changes may often also include this type of middle ground. Questions about punctuated equilibrium approaches have been raised in recent years by those who emphasize that change is likely more continuous than episodic (e.g., R. Thomas, Sargent, & Hardy, 2011; Weick & Quinn, 1999).

The Dialectic Motor

The dialectic motor describes organizational change as the result of conflict between opposing entities. New ideas and values must directly confront the status quo. This motor builds from the Hegelian process of a thesis and

antithesis coming into direct conflict. There are then several paths that may be taken, including separating the thesis and antithesis, attempting to create a synthesis of them, and/or attempting to embrace the differing perspectives (e.g., Baxter & Montgomery, 1996; Seo et al., 2004). Some argue that achieving a synthesis that appears to close off change may be less productive than developing organizational capacity to embrace conflicting approaches (cf. Bartunek, Walsh, & Lacey, 2000).

The dialectic motor often drives cognitive and political change theories and plays a prominent role in schematic change theories and communicative change models. It also forms the basis for a number of the OD approaches outlined in the next section of this chapter.

Schematic Change

Schematic models of change build from an understanding of individual cognitive processing to understand how changes occur in shared schemas. Schemas are cognitive frameworks that provide meaning and structure to incoming information (Mitchell & Beach, 1990). Organizational change is categorized by the level of change in the shared schemas. First-order change occurs within a shared schema and second-order change involves change in the shared schema (Watzlawick, Weakland, & Fisch, 1974).

Change in schemas typically occurs through a dialectic process triggered by the misalignment of a schema in use with the context (e.g., Labianca, Gray, & Brass, 2000). If a situation does not fit within an expected schematic framework, the person shifts to an active processing mode (Austin, 1997). In this mode, the individual uses environmental cues to generate a new schema or modify an existing one. The direct comparison of the schema (thesis) with the context (antithesis) creates the change.

This schematic dialectic is applied to organizational change through change in shared schemas (Rerup & Feldman, in press). Bartunek (1984) proposed that organizational schema change required a direct conflict between the current schema and the new schema. Such conflict between schemata underlies large-scale organizational changes, including major industry change (Bacharach, Bamberger, & Sonnenstuhl, 1996), organizational breakup (Dyck & Starke, 1999), organizational identity change (Dutton & Dukerich, 1991; Reger et al., 1994), and organizational responses to new economic systems (Kostera & Wicha, 1996).

Identity and Change

Another dialectic tension can emerge between organizational identities and shifting environments or new

knowledge. Patterns of change can emerge from these interactions. This work tends to view change as a tension between existing identities and external pressures that challenge those identities (Corley & Gioia, 2004; Nag, Corley, & Gioia, 2007).

Communicative Change Theories

Drawing from notions of social construction (Berger & Luckmann, 1966) and structuration (Giddens, 1984), several theorists have begun to consider change as an element of social interaction. Change is recognized and generated through conversation and other forms of communication (Bushe & Marshak, 2009; J. D. Ford, 1999a; J. D. Ford & Ford, 1995, 2008; 2009; Phillips, Lawrence, & Hardy, 2004). Organizations consist of a plurality of perspectives that are revealed through conversation (Hazen, 1994) that forms the context for all organizational action. When different perspectives meet through conversation, either a synthesized perspective is generated or one perspective is spread. New and old perspectives coexist within the organization at the same time as the newer synthesized understanding diffuses through multiple conversations (Gilmore, Shea, & Useem, 1997). Whether the end result is synthesis or diffusion is partially determined by the significance of the perspectives and interaction to the identities of the participants (Gergen & Thatchenkery, 1996). Significant organizational change typically requires new organizational language that results from the conversational dialectic (Barrett, Thomas, & Hocevar, 1995) and that realigns discordant narratives and images (Faber, 1998).

The Evolutionary Motor

The evolutionary motor focuses on change in a given population over time. It involves a continuous cycle of variation, selection, and retention. Evolutionary theories of organizational change focus on environmental conditions that create inertial pressures for organizational change. Change theories built around this motor begin with the assumption that one must understand the environmental setting of an organization in order to understand the dynamics of change. Organizations evolve based on their ability to respond and adapt to these powerful external forces. In the early 1990s, the evolutionary motor was most evident in population ecology models. However, it is also the driving force in recent research on the rate of organizational change and in theories of institutional change.

Internal Change Routines

Research on organizational routines applies variation, selection, and retention to intraorganizational processes

by considering how individual actions are selected and retained within the population of organization members.

Nelson and Winter (1982; also see Feldman, 2000; Feldman & Pentland, 2003) propose that organizations develop routines, or patterns of action, that drive future action. Routines become more developed and complex as they are used. Routines that involve changing current routines are called modification routines. Like other organizational routines, modification routines can be relatively stable over time, leading the organization to approach organizational change in a consistent manner. Well-developed routines of organizational change enable an organization to adjust to different demands for change by modifying the content of the change but using a consistent process to manage the change (Levitt & March, 1988).

Experience with a certain type of change enables an organization to refine its routines for implementing that type of change. As a result, the organization develops expertise with that type of change and may be more likely to initiate similar changes in the future. For example, in their study of the Finnish newspaper industry, Amburgey et al. (1993) found that experience with a certain type of organizational change increased the likelihood that a newspaper would initiate a similar type of change again. They argued that this process occurs because the organization develops competence with the change type. Thus, costs of change are lowered and the organization is likely to see the change as a solution to an increasing number of problems.

Hannan and Freeman (1984) use the notion of organizational routines to explain how organizations attempt to increase the reliability of their actions and create conditions of stability in relatively unstable environments. They posit that these routines institutionalize certain organizational actions and create organizational inertia, which hinders the organization's ability to change. Kelly and Amburgey (1991) extend this model by showing that the same routinization processes that create inertia can also create momentum. Routines that institutionalize a certain rate of change create conditions that encourage change consistent with those routines. While disruptions in routines brought about by organizational change can destroy competencies (Levitt & March, 1988), that same organizational change can create competencies that make future organizational change more effective (Amburgey & Miner, 1992).

Brown and Eisenhardt (1997) found that organizations establish an internal pacing mechanism to operate in a constantly changing environment. For example, managers plan to release new versions of their products every nine months or set goals targeting a certain amount of

income that needs to come from new products each year. While organizations continue to respond to environmental changes they may devote a larger percentage of their resources to developing internal capabilities to change regardless of industry pressures.

Institutional Change

Institutional theory is often associated with stability rather than with change. Organizations grow more similar over time because the institutional environment provides resources to organizations that conform to institutional norms that create barriers to innovations (North, 1990; Zucker, 1987). However, as Greenwood and Hinings (1996) note, theories of stability are also theories of change.

Institutional theory proposes that organizational actions are determined by the ideas, values, and beliefs contained in the institutional environment (Meyer & Rowan, 1997). Strong institutional environments influence organizational change by legitimating certain changes and organizational forms (DiMaggio & Powell, 1991). In order for an organizational change to be successful, it needs to be justified within the institutional system of values (D'Aunno, Sutton, & Price, 1991). In addition, broader institutional forces sometimes trigger organizational change (Greenwood & Hinings, 1993) or provide comparisons that in turn prompt such change (Greve, 1998; Lounsbury & Crumley, 2007).

Institutional change theories rely on the evolutionary motor to understand the dynamics of change. Isomorphic pressures on organizations act as a selection and retention process for validating organizational changes. However, institutional theorists emphasize that organizational actors play a part in creating the institutional forces that restrain them (DiMaggio & Powell, 1991; Elsbach & Sutton, 1992; Hargrave & Van de Ven, 2006; Oliver, 1991; Suchman, 1995). Thus, institutional models of change have begun to build teleological motors into theories of institutional change by considering the strategic actions of institutional actors (Bloodgood & Morrow, 2000; Creed, DeJordy & Lok, 2011; Creed, Scully, & Austin, 2002; Johnson, Smith, & Codling, 2000).

Integrating Change Process Motors: Institutional Entrepreneurship

Since 2003, institutional entrepreneurship (Battilana, Leca, & Boxenbaum, 2009; Hardy & Maguire, 2008) has been one of the most active areas of organizational change research. Institutional entrepreneurship models are particularly fascinating because of their multiple motors of change. Writers have begun to expand upon the

conventional evolutionary motor of institutional change by integrating institutional models with the dialectic motor (Mutch, 2007; Seo & Creed, 2002), teleologic motor (Phillips & Tracey, 2007), and even the life-cycle motor (Misangyi, Weaver, & Elms, 2008). The resultant models explore how change agents are simultaneously constrained by and influence their environment. The integrated motors of change have led to connections between institutional change and strategy (Jarzabkowski, 2004), power (Levy & Scully, 2007), discourse (Lawrence & Phillips, 2004; Suddaby & Greenwood, 2005), and organizational routines (Reay, Golden-Biddle, & Germann, 2006).

Summary of Change Process Research

Change process theory continues to develop and evolve. New approaches to understanding change processes continue to emerge from each change motor identified by Van de Ven and Poole. Contemporary theorizing frequently draws from multiple motors with comparatively more attention to the teleologic motor. Attempts to understand such multilevel issues as institutional entrepreneurship, innovation, and strategic change require that researchers build links between theories of individual change and theories of organizational change. Interactions between research on individual resistance to change, organizational-level political pressures, and institutional constraints have led to further clarification of change process at each level. Thus, multilevel theorizing can expand our understanding of change processes and may lead to the identification of additional change motors.

SAMPLES OF CONTEMPORARY OD INTERVENTIONS

Several approaches to intervention characterize contemporary OD. It is neither possible nor desirable to give a complete list here. In this section we identify some OD interventions that have been prominent in the past 15 to 20 years. Our review includes articles published in both academic and practitioner journals. It is not meant to be exhaustive, but illustrative of the implementation approaches that have drawn the most attention in the early 21st century. These approaches include appreciative inquiry, learning organizations, large-scale interventions, and employee engagement.

Appreciative Inquiry

Cooperrider and Whitney (2007, p. 75) described appreciative inquiry as “the cooperative, co-evolutionary search for the best in people, their organizations and

communities, and the world around them. It involves systematic discovery of what gives ‘life’ to an organization or community when it is most effective, and most capable in economic, ecological and human terms.”

Cooperrider and Srivastva (1987) introduced appreciative inquiry (AI) as a complement to other types of action research. Since that time, AI has emerged as a widely used OD intervention. According to some practitioners, appreciative inquiry is one of the most widely used OD interventions in the world (Watkins & Mohr, 2001).

Appreciative inquiry builds from several important assumptions. First, social systems are socially constructed; people create their own reality through dialog and enactment. Second, every social system has some positive working elements and people draw energy for change by focusing on positive aspects of the system. Third, by focusing on building consensus around these positive elements, and avoiding discussion of the negative aspects of the system, a group will create momentum and energy toward increasing the positives there.

Recent writings on appreciative inquiry highlight the social constructionist focus on dialog as a way to enact a reality. Most articles and books on appreciative inquiry use case studies and frameworks for appreciative discussions to help practitioners lead appreciative inquiry interventions (Barrett, 1995; Bushe & Coetzer, 1995; Cooperrider & Whitney, 2005; Rainey, 1996; Srivastva, Cooperrider, & Associates, 1990). Driving these case studies is the observation that by focusing on the positive elements about “what is,” participants create a desire to transform the system. The close relationship between the appreciative inquiry process and organizational culture and language invites strong transformations in mindset and action. This can have unintended consequences, positive and negative (Bushe & Kassam, 2005; Fitzgerald, Oliver, & Hoxsey, 2010), and calls for skillful facilitation.

Appreciative inquiry is playing an increasingly important global role. It has been successful as an approach to global consultation efforts (e.g., Barrett, 1995; Barrett & Peterson, 2000), in part because it emphasizes appreciation of different approaches. Mantel and Ludema (2000), for example, describe how appreciative inquiry creates new language that supports multiple positive ways of accomplishing things. This is particularly important in a global setting in which people are operating out of very different perspectives on the world (Tenkasi, 2000).

Large Group Interventions

As noted at the beginning of this chapter, the primary conceptual basis for OD has been action research. As it was

originally designed, action research customarily begins by searching out problems to be addressed. However, Bunker and Alban (1997) recounted that by the 1970s some concern had been raised about this approach; Ronald Lippitt believed that starting with problems caused organization members to lose energy, and to feel drained and tired. (Similarly, appreciative inquiry starts with positive, rather than negative features of an organization.)

Lippitt saw problem solving as past oriented. He believed that focusing on the future, rather than the past, would be more motivating. Thus, he began to engage organization members in thinking about their preferred futures (Lippitt, 1980, 1983). Attention to future organization members' desire is a first major emphasis of many large group interventions. A second emphasis is on gathering "the whole system" or, if the whole system is not possible, representatives of a large cross-section of the system (at least 10% of it), to contribute to future planning. One reason for the prominence of large-group interventions is recent emphasis on organizational transformation. Many (though not all) large-group interventions are designed to help accomplish transformation, based on the expectation that in order to transform a system, sufficient numbers of organization members with power to affect transformational processes must participate in change efforts.

Filipczak (1995) notes that the typical aims of large-group interventions include such foci as changing business strategies, developing a mission or vision about where the company is headed in the next century, fostering a more participative environment, and/or initiating such activities as self-directed work teams or reengineering the organization.

A wide variety of large-group interventions have been developed in recent years (e.g., Bunker & Alban, 1997, 2006; Holman et al., 2007; Weber & Manning, 1998). One useful classification scheme for them was developed by Bunker and Alban (1997, 2006), who distinguish large-group interventions according to whether they are focused on proactively creating a desired future together, redesigning work together as a whole system, and bringing the system together to work on immediate problems and issues. A list of many of these, along with a very brief summary description of each, is presented in Table 16.2. To give a more concrete sense of the large-group interventions, we will briefly introduce two of them: Open Space Technology and the World Café.

Open Space Technology

Open Space Technology (OST; www.openspaceworld.org/) was developed by Harrison Owen (1991, 1992)

TABLE 16.2 Examples of Types of Large-Group Interventions and Summaries of Their Uses

Examples of Large-Group Methods for Proactively Creating the Future	Examples of Large-Group Methods for Work Design	Examples of Large-Group Methods for Whole-Scale Participative Work
<p>The Search Conference: Participative events that enable diverse organization members to identify their desired future and develop strategic plans they will implement that they expect to accomplish this future.</p> <p>Future Search: A 3-day conference aimed at helping representatives of whole systems envision a preferred future and plan strategies and action plans for accomplishing it.</p> <p>Whole-Scale Change: A flexible approach involving interactions of large and small groups to allow an organization to build a common database and form a common intention for action.</p> <p>ICA Strategic Planning Process: A method designed to maximize the participation of community members in change processes that affect them by means of focused conversation, workshops, and event planning.</p> <p>Appreciative Inquiry Summit: Method for conducting appreciative inquiry in short, focused sessions.</p>	<p>The Conference Model: A series of conferences through which organization members study the correspondence between their own work and their desired future and develop new designs for work.</p> <p>Participative Design: Workshops based on the search conference model in which groups of employees participate democratically in designing, managing, and controlling their own work.</p>	<p>SimuReal: Workshops in which organizational members work on real problems in simulated settings that enable them to learn how their organization approaches tasks and to determine what they would like to change.</p> <p>Open Space Technology: A loosely structured meeting that enables groups of organization members ranging in size from a small group to 1,000 develop their own agendas in relationship to prespecified organizational concerns.</p> <p>Work Out: Meetings in which groups of organization employees brainstorm ways to solve an organizational problem. Managers must accept or reject solutions in a public forum at the conclusion of the meeting.</p> <p>The World Café: Engages people in dynamic conversations around questions that matter to their lives and work.</p>

Source: Adapted from Bartunek, Balogun, & Do (in press). More information about each large-group intervention may be found in Bunker & Alban (1997, 2006), Holman et al. (2007), and www.change-management-toolbook.com/mod/book/view.php?id=74&chapterid=6

and expanded over time (Owen, 2007; Seo et al., 2004). Its purpose is “to enable groups to address complex, important issues as a high-performing system by inviting people to take responsibility for what they love for a few hours, a few days, or as an everyday practice” (Holman et al., 2007, p. 677). It is appropriate “in situations where a major issue must be resolved, characterized by high levels of complexity, high levels of diversity (in terms of the people involved), the presence of potential or actual conflict, and with a decision time of yesterday” (Owen, 2007, p. 139). Its (loose) conceptual basis lies in research dealing with “self-organization, complex adaptive systems, dissipative structures and the like” (Owen, 2007, p. 145), as introduced by natural scientists such as Kaufmann, Prigogine, and Gel-Mann.

OST has been used in more than 140 countries in a large variety of groupings. A group of 5 to more than 1,000 people assemble in a room that has enough chairs for all participants. The facilitator describes the reason participants are gathered. Second, after briefly describing the process, rules, and norms, the facilitator asks participants to identify issues related to the theme for which they have genuine passion, and for which they will take real responsibility. They are asked to come out into the center of the circle, take a piece of paper and a magic marker, and write down a short title and their name. Then they announce their topic and name, and post the piece of paper on a wall labeled “Community Bulletin Board.”

The next step is to invite the participants to approach the board and sign up for any and all discussions that they are interested in attending. Based on the sign-up, people form small groups, discuss the issues, and construct written reports. Finally, the reports are collected from all groups, summarized, and fed back to the entire assembly. One law and four principles guide the group discussion. The law of the two feet encourages people to use their two feet and go to some more productive place if during the course of the gathering they find themselves neither learning nor contributing. The four principles increase flexibility and creativity: (a) whoever comes are the right people (free composition), (b) whatever happens is the only thing that could have happened (free content), (c) whenever it starts is the right time (little time constraint), (d) when it is over, it is over (free closure).

According to its Web site and published articles (e.g., Owen, 2007), OST is being used in businesses, in local communities and, particularly at this moment, to provide space for “peace and high performance,” especially but not only with regard to the Middle East.

World Café

As its Web site (www.theworldcafe.com/what.htm) notes, the World Café is “an innovative yet simple methodology for hosting conversations about questions that matter. These conversations link and build on each other as people move between groups, cross-pollinate ideas, and discover new insights into the questions or issues that are most important in their life, work, or community.” Conceptually it is based, at least loosely, on the work of Maturana and Varela (1987) regarding the power of conversation to shape the future (Brown & Isaacs, 2005).

The World Café focuses around sets of table conversations. The World Café process works as follows: A group of participants sit at a table and discuss an important topic. There is butcher paper available there for the participants to leave notes. Then all but one of the participants, the host, move on to another table, to deepen the conversation, either about the original topic or about a related one whose answers build on the first set of answers.

In order for the conversation to be productive, the World Café process uses seven principles outlined in detail by Brown and Isaacs (2005).

1. *Set the context:* Clarify the purpose and broad parameters within which the dialogue will unfold.
2. *Create hospitable space:* Assure the welcoming environment and psychological safety that nurtures personal comfort and mutual respect.
3. *Explore questions that matter:* Focus collective attention on powerful questions that attract collaborative engagement.
4. *Encourage everyone’s contribution:* Enliven the relationship between the “me” and the “we” by inviting full participation and mutual giving.
5. *Cross-pollinate and connect diverse perspectives:* Use the living system dynamics of emergence through intentionally increasing the diversity and density of connections among perspectives, while retaining a common focus on core questions.
6. *Listen together for patterns, insights, and deeper questions:* Focus shared attention in ways that nurture coherence of thought without losing individual contribution.
7. *Harvest and share collective discoveries:* Make collective knowledge and insight visible and actionable.

Brown, Homer, and Isaacs (2007) note that the World Café has been used successfully in a wide variety of contexts. These include teachers and administrators inquiring together into improving student performance, a consumer products company planning to improve market share,

member associations discovering what is important to members, and planning retreats and meetings.

Learning Organizations

The idea that organizations and/or their members learn has been present for decades. However, most scholarly attention to learning focused on learning as an adaptive change in behavioral response to a stimulus, particularly the learning of routines (e.g., Levitt & March, 1988). Learning was not necessarily viewed as desirable for the organization.

In the 1970s, however, Argyris and Schön (1978) introduced learning in a positive way, as a means of improving organizations. Argyris and Schön and others (e.g., Feldman, 2000) argued that learning must include both behavioral and cognitive elements and involve the capacity to challenge routines, not simply enact them. This formulation was the basis for the learning organization, which in recent years has been one of the most popular business concepts. Communities of researchers and practitioners who study and practice learning organizations have emerged and grown rapidly (Easterby-Smith, 1997; Tsang, 1997).

Peter Senge's best-selling book, *The Fifth Discipline*, and workbooks that have followed, including *The Fifth Discipline Fieldbook* (Senge, Kleiner, Roberts, Ross, & Smith, 1994) and *The Dance of Change* (Senge, Kleiner, Roberts, Ross, Roth, & Smith, 1999), have been the written source most responsible for bringing the learning organization into the mainstream of business thinking (Seo et al., 2004). For Senge (1990), a learning organization is "an organization that is continually expanding its capacity to create its future" and for which "adaptive learning must be joined by generative learning, learning that enhances our capacity to create" (p.14). Senge described five different "disciplines" as the cornerstone of learning organizations:

1. *Systems thinking*: Learning to better understand the interdependencies and integrated patterns of our world.
2. *Personal mastery*: Developing commitment to lifelong learning and continually challenging and clarifying personal visions.
3. *Mental models*: Developing reflection and inquiry skills to be aware of surface, and test the deeply rooted assumptions and generalizations that we hold about the world.
4. *Building shared vision*: Developing shared images of the future that we seek to create and the principles and guiding practices by which to get there.
5. *Team learning*: Group interaction that maximizes the insights of individuals through dialogue and skillful

discussion and through recognizing interaction patterns in teams that undermine learning.

The workbooks describe ways to accomplish these disciplines and challenges to sustain the momentum of learning. For example, Senge et al. (1994) describe "left-hand column" and "ladder of inference" methods to help increase the ability to recognize one's mental models. They describe dialogue as a way group members can learn to think together to foster team learning, and they describe ways people might draw forth their own personal visions as a way of developing personal mastery.

In recent years the emphasis of learning organizations, especially those associated with the Society for Organizational Learning (www.solonline.org), has expanded. The SOL Web site, for example, emphasizes "Conscious learning in three domains: collective knowledge creation; practical application of knowledge; and community building." Further, these emphases are being expressed in movements toward sustainability around the world (e.g., Senge, Smith, Kruschwitz, Laur & Schley, 2008), under the assumption that such sustainability is crucial for organizations' continued learning and development.

Employee Empowerment

Although there have not been agreements on standard intervention processes to develop employee empowerment, there is little doubt that achieving empowerment is a major emphasis of much OD and similar consulting. OD work in employee empowerment connects authority and accountability with engagement. It has been emphasized since Peter Block's (1987) influential book, *The Empowered Manager*.

There is considerable variation in how empowerment is understood. For example, Ehin (1995) describes empowerment as a frame of reference that incorporates deep, powerful, and intimate values about others, such as trust, caring, love, dignity, and the need for growth. In the context of work teams, Mohrman, Cohen, and Mohrman (1995) describe empowerment as the capability of making a difference in the attainment of individual, team, and organization goals, and suggest that it includes adequate resources and knowledge of the organization's direction. Thomas and Velthouse (1990), followed by Spreitzer (1996), focus on empowerment in terms of cognitive variables (task assessments) that determine motivation in individual workers.

Just as there are multiple definitions of empowerment, there are multiple mechanisms in organizations that may be used to help foster it. These may include structural

factors (Spreitzer, 1996) and attempts to redesign particular jobs so that they include more of the individual task components that make up empowerment (Thomas & Velthouse, 1990). Most frequently, the means by which empowerment is discussed as being fostered in organizations is through participation in organizational decision making (e.g., Hardy & Leiba-O'Sullivan, 1998), and enhancement of the organizational mechanisms (such as knowledge, resources, or teams) that help enable employees participate in decision making (Bowen & Lawler, 1992). In recent years, there has been recognition of the important role of social media in engaging and empowering employees (Bernoff & Schadler, 2010). Further, contemporary discussion of empowerment sometimes uses the language of engagement (e.g., Axelrod, 2010), referring at least in part to ensuring that employees' voices count in conversations and that there is fairness in their exchange with their superiors.

IMPLEMENTATION THEORIES

Implementation theories address how actions generate change and what actions can be taken to initiate and guide change. Porras and Robertson distinguished types of implementation based on whether they focused on intervention strategy, procedure, or technique. Similar to the approach taken by Van de Ven and Poole (1995), we focus on four "motors" of change, four primary implementation approaches that are expected to accomplish the desired change. These motors come primarily from literature written for practitioners rather than literature written for academics. They are participation, self-reflection, action research, and narrative. Participation and action research have been cornerstones of OD practice for decades (French & Bell, 1999). However, what they mean in practice has evolved. Self-reflection and narrative, while implicit in some earlier OD work, have become much more prominent recently. Not surprisingly, these methods play prominent roles in the OD interventions we described above.

Participation

Participation in organizational change efforts and, in particular, participation in decision-making formed the earliest emphases of OD (French & Bell, 1999). Such participation is still viewed as important, but there has been expansion in ways such participation is understood and takes place, along with a greater awareness that

employees do not always wish to participate in change efforts (Neumann, 1989).

Earlier rationales for participation often centered around the expectation that employees were more likely to accept decisions in which they had participated. Now, however, the rationale for participation is somewhat different, as expectations of the role of employees in participation expand. In particular, there is now much more explicit emphasis on employees participating in *inquiry* about their organizations and contributing necessary *knowledge* that will foster the organization's planning and problem solving. This is illustrated in the roles of employees in the various large-scale interventions, as various participants are expected to reflect on and contribute knowledge about the organization's past as well as its future (e.g., in search conferences). It is also illustrated in the expectation that employees contribute to learning processes in their organizations, for example, through the various exercises designed to foster their own capacity and in their contribution to learning histories. Creative new means of participation such as General Electric's workout sessions give employees much more responsibility for solving problems and acknowledge much more employee knowledge than was often the case in the past.

Self-Reflection

The growing interest in large-scale change in organizations has been accompanied by a similar interest in leadership of organizational transformation, and, thus, in the development of leaders who can blend experience and reflection in order to create lasting organizational change. Torbert (1999) and Quinn et al. (2000) suggest that a primary means by which leaders accomplish this is through self-reflection and self-inquiry.

Torbert (1999) suggests that leaders need to develop the ability to reflect while acting so that they can respond to changing conditions and develop new understandings in the moment. Individual transformation involves an awareness that transcends one's own interests, preferences, and theories, enabling more holistic understanding of patterns of action and thought. Transformational leaders determine the appropriate method of transformation by cultivating a strong understanding of the context, including tradition, vision, and organization and individual capabilities. The exercise of transforming leadership affects the organization's capacity for transformation.

Advanced Change Theory (Quinn et al., 2000) proposes that by modeling a process of personal transformation, change agents enable deeper organizational change.

This process demands that change agents be empowered to take responsibility for their own understanding (Spreitzer & Quinn, 1996) and develop a high level of cognitive complexity (Denison, Hooijberg, & Quinn, 1995). This generally requires a change in values, beliefs, or behaviors, which is generated by an examination of internal contradictions. The leader creates opportunities for reflection and value change through intervention and inquiry. The leader is constantly shifting perspectives and opening up values and assumptions for questioning. The more skilled organization leaders are at generating deep personal cognitive change, the more likely it is that the leaders will support and/or create deep organizational change.

One particularly interesting development is that of “presencing,” based on assumptions of “Theory U” (Senge, Scharmer, Jaworski & Flowers, 2004; Scharmer, 2007), that the way we attend to a situation determines how it unfolds. As stated on its Web site (www.presencing.com), “Presencing,” a blend of the words *presence* and *sensing*, refers to “the ability to sense and bring into the present one’s highest future potential.” It is based on the assumption that leaders typically have a “blind spot” regarding the source from which effective leadership and social action come into being. It involves a series of “movements,” including holding the space of listening, observing, sensing, presencing, crystallizing, prototyping, and performing, aimed at helping individuals (and groups) come over time to understand this source and develop capacities to bring their deepest selves to the situations they encounter in order to foster their working with others to cocreate a desired future.

Action Research

Action research consists of a set of theories of changing that work to solve real problems while also contributing to theory. While the original models of Action Research emphasized the solution of problems, models of action research developed in later years include a wider array of emphases. In particular, many contemporary action research models propose that change can be triggered through a process of direct comparison between action and theory.

Participatory Action Research

Participatory Action Research (PAR) was developed largely by Whyte (1991) and his colleagues. It refers to a process of systematic inquiry in which those experiencing a problem in their community or workplace participate with researchers in deciding the focus of knowledge

generation, in collecting and analyzing data, and in taking action to manage, improve, or solve their problem.

Action Science

Dialectic change theories envision change as the outcome of conflict between a thesis and antithesis. Action science focuses on how to bring the thesis and antithesis into conflict. Argyris and Schön’s (1974) Model II learning and Argyris, Putnam, and Smith’s (1985) Action Science model provide a common base for dialectic action science methods. Change is triggered by calling attention to discrepancies between action and espoused values. Highlighting differences between “theories in use” and “espoused theories” generates the impetus for change. Argyris focuses on processes that enable double-loop learning and awareness of underlying values guiding action. Individuals work to expose the mental models driving their action and to identify the values and actions through which they influence their context.

Several other writers have expanded this approach to change by highlighting the importance of understanding how action is embedded in a broader system of values and meaning. For example, Nielsen (1996) calls for “tradition-sensitive” change dialectic strategies in which the change agent directly links the change with biases in the shared tradition system.

Action Learning

Action learning, like action science, has a goal of changing behavior by comparing behaviors and theories. In an action science intervention, the individual compares theories in use with espoused theories. In an action learning intervention, the dialectic is between theoretical knowledge and personal experience. Revans (1980) outlines a process in which action learning groups work to understand social theories and ideas by applying them to a real situation. Participants use the theory to understand the logical implications of their experience and use the experience to internalize, refine, and make sense of the theory. Because of its group emphasis, action learning focuses on interpersonal interactions and their effect on project outcomes (Raelin, 1997).

Narrative/Rhetorical Intervention

Narrative interventions highlight the role that rhetoric and writing can play in generating organizational change (J. D. Ford & Ford, 2008; Oswick, Grant, Marshak, & Wolfram Cox, 2010), and are probably the predominant type of intervention motor currently in use. This approach to

change finds its theoretical roots in sensemaking (Weick, 1995) and interpretive approaches to organizations (Boje, 1991). Organizational actors partially create their reality through the retrospective stories that they tell about their experience and through future-oriented stories that they create as a pathway for action. Convergence of narratives by organization members drives collective sensemaking (Boyce, 1995).

Organizational change can be generated through sharing of stories and building consensus around new images of the future in which the stories shift (J. D. Ford & Ford, 2008). The stories, thus, offer a goal toward which organization actors can work, and the role of the change agent is to assist organization members in reconceiving their understandings (Frost & Egri, 1994) by creating new stories. This approach also opens up our view of organizational change as something that is continuous rather than episodic. The sensemaking process captured in stories generates change within the continuous “organization becoming” process (Peirano-Vejo & Stablein, 2009). J. D. Ford and Ford (1995) identify four types of conversations that drive change: initiative, understanding, performance, and closure. Initiative conversations start a change process, understanding conversations generate awareness, performance conversations prompt action, and closure conversations acknowledge an ending.

Several current OD practices rely on a narrative theory of changing (Ford, Ford, & D’Amelio, 2008; Marshak

& Grant, 2008). Appreciative inquiry draws on narrative OD theories by challenging organization members to generate local theories of action. Barry (1997) identifies strategies from narrative therapy that can enable organizational change. These include influence mapping, problem externalization, identifying unique outcomes, and story audiencing. Using the case of a high-technology research organization, O’Connor (2000), illustrates how stories told during a strategic change link the change with the past to highlight anticipated future problems and accentuate how the past and present differ.

These interventions, and similar ones, continue to grow in popularity. However, there is little to no scholarly research being carried out to assess their effectiveness and little to no change process theorizing being used to understand their underlying dimensions (Bartunek et al., in press), and this reinforces separations between change process and implementation theory.

THE IMPLEMENTATION/CHANGE PROCESS THEORY CONNECTION

It is possible to construct a rough map of the links between particular implementation motors, interventions, and change processes, especially as implementation motors would likely occur in the interventions described above. Such a rough map is depicted in Table 16.3. It

TABLE 16.3 Possible Relationships* Between Change Process Models and Implementation Models as These Are Expressed in Contemporary Intervention Approaches

	Implementation Models			
	Participation	Reflection	Action Research	Narrative
Types of Interventions in which Each Implementation Model Is Used	Often used in: Appreciative Inquiry, Large-Group Interventions, Learning Organizations, Empowerment	Often used in: Appreciative Inquiry, Large-Group Interventions, Learning Organizations	Often used in: Learning Organizations, Empowerment	Often used in: Appreciative Inquiry, Large-Group Interventions, Learning Organizations
Change Process Motors				
Teleological (e.g., strategy, cognitive framing, change momentum, continuous change)	xx	xx	xx	
Life cycle (e.g., punctuated equilibrium/transformation)		xx	xx	
Dialectic (e.g., schema change, communication change)			xx	xx
Evolutionary (e.g., internal change routines, institutional change)			xx	

*Possible ways of implementing each change process model by means of one or more of the implementation approaches are indicated by xx.

indicates that implementation strategies have been developed primarily for the teleological motor, as this is expressed in its multiple forms. However, at least one OD intervention potentially applies to each of the other change process motors.

THE CHANGE PROCESS THEORY/ IMPLEMENTATION THEORY DIVIDE

The fact that some OD interventions are applicable to the different change process theories means that they represent potential means for fostering these different types of change. It does not mean that authors who describe the different types of change motors reference OD work or that the implementation models reference the change process theories. In the great majority of cases there is no explicit connection between them. To the contrary, we believe that there is a fairly strong divide between those who focus on change process models and those who focus on particular interventions and their underlying implementation models, with relatively little information passing from one knowledge network to the other. In this section of the chapter we will describe some indicators of this divide. However, we will also suggest some signs of optimism that it might be bridged.

Indicators of the Divide

Journal Publication

In 2003, we used the journal *Organization Science* as a model of a type of “bridge journal” that was publishing articles using both change process and implementation theory approaches. This dual publication was intentional. As its first editors noted at the beginning of publication of the journal, *Organization Science* was founded to “enhance research relevance . . . encourage the joining of theory to practice, and anchor organization research in relevant problems” (Daft & Lewin, 1990, pp. 2, 9).

However, over the years *Organization Science* changed its focus. This was recognized in Daft and Lewin’s (2008) acknowledgment that *OS* has stepped back from its original objective to “enhance research relevance . . . and encourage the joining of theory to practice” (Daft & Lewin, 1990, pp. 2, 9). They argued that this goal “was unrealistic and has not been realized . . . *OS* has not been and should not strive to be an immediate source of knowledge for practical implications” (Daft & Lewin, 2008, p. 177).

Other top-tier journals also do not focus on practice. Rynes (in press-a) notes that one reason is that top-tier

journals tend to hold to “scientific” models of publishing more than others do, while another is such journals’ “growing emphasis on theoretical contribution as a publication requirement” (Rynes, in press-a). This tends to make top-tier journals less accessible to practitioners.

Orientation of Universities

There is considerable awareness of the strong emphasis of universities on top-tier publication, and strong incentives for academics to publish in such journals as much as possible. These are “countable,” and a means, however crude, of comparing academics’ output with each other. Such publications are also much more visible than other types of work (e.g., teaching, service) that academics do, and thus are more likely to facilitate movement across universities for those who seek to advance their careers by this means.

Orientation of Practitioners

Even if academics were to write more for practitioners, it isn’t clear that this would have immediate positive impacts. For example, practitioners often do not read scholarly work, or if they do, they may not believe it (Rynes, Colbert, & Brown, 2002). This is even true of organization development practitioners who as part of their membership in their professional organization, NTL Institute for Applied Behavioral Science, do not always read the bridge journal, *Journal of Applied Behavioral Science*, that they receive as part of their membership (Bartunek & Schein, 2011). This appears to be, at least in part, because many practitioners have not had the kinds of academic training that would make the writing and epistemological style of such journals accessible to them.

Indicators of Optimism That the Divide May Be Crossed

The issues listed above are serious. However, they are not definitive. There are many signs of hope as well (cf Rynes, in press-b).

Evidence-Based Management

One sign of hope is the recent development of Evidence-Based Management (Rousseau, in press) and its associated movement (www.evidence-basedmanagement.com/index.html). This movement, which is consciously including practitioners as well as academics, is aimed at helping to communicate across academic–practitioner boundaries in ways that are fruitful for both theory building and practice.

Scholar-Practitioners

Another sign of hope is the increasing number of people who are referring to themselves as scholar-practitioners (e.g., Wasserman & Kram, 2009). Many of these scholar-practitioners are being trained in executive and practitioner-oriented doctoral programs, where they are learning to read scholarly literature, so do not find it as foreign as many practitioners (including consultants) do. There is at least a potential that, to the extent they develop change initiatives and implementation theories underlying them, they will be able to communicate these across boundaries more effectively than has often been done in the past.

Journals

We noted the *Journal of Applied Behavioral Science* as an intended bridge journal between academic scholarship and practice. Other journals with this intended purpose are beginning to emerge as well, including, most prominently, the Society for Industrial & Organizational Psychology's (SIOP) *Industrial and Organizational Psychology: Perspectives on Science and Practice*. This journal, which began publication in 2008, focuses on "interactive exchanges on topics of importance to science and practice in our field" (www.siop.org/journal/siopjournal.aspx). It includes focal articles and commentaries from both academics and practitioners.

While this journal does not yet focus directly on implementation theory, it does open up the possibility of work based on such theories being used to comment on models arising from change process theory perspectives.

Insider/Outsider Joint Research

Further, various types of collaborative research involving both academics and practitioners (e.g., Bartunek & Louis, 1996; Shani, Adler, Mohrman, Pasmore, & Stymne, 2008) have become more and more acceptable as legitimate types of scholarship. In publications of such collaborative research, it is possible for change process theorizing to be combined with descriptions of implementation theories and their enactment. This type of bridging shows particular promise in enabling implementation and change process approaches to be in dialog in some way.

Tempering the Optimism

While there is reason for optimism that the academic/practitioner divide can narrow, there remains a significant barrier that remains as strong as ever. Mindsets regarding credibility remain entrenched on either side of the divide. Academics and practitioners alike continue to discount the quality and relevance of their counterparts' work. One

can see this barrier on display in executive education programs. These programs bring together academic faculty and practitioner faculty and often the participant evaluations tell an interesting story. The academic faculty are faulted for not making connections to the real world and the practitioner faculty are faulted for not offering new conceptual insights. When confronted with these comments, executive faculty, who are usually quite successful in their chosen field, appear to discount them. The academic faculty are tempted to claim that their job is to instill critical thinking skills and the participants should be able to make connections on their own. The practitioner faculty are tempted to claim that their experience is hard-won and should provide key lessons for the participants. There are, of course, successful executive educators who have learned to speak both languages. However, as long as the prevailing academic mindset continues with the unstated assumption that idea creation should be held in higher regard than idea translation, we temper our optimism for greater knowledge movement between academics and practitioners.

In our 2003 chapter, we discussed differing knowledge validation methods as a barrier to knowledge transfer between academics and practitioners. The epistemological differences we observed in articles at the time are also consistent with the executive education example. Geertz's (1983) distinction between "experience-near" and "experience-far" concepts captures this difference. People use experience-near concepts to explain what they experience and describe the experience to others. The goal is to communicate a sense of the immediate context. Specialists use experience-far concepts to map their observations and categorize them as part of a larger abstract body of knowledge. Academics often dismiss experience-near approaches as not rigorous enough; practitioners often dismiss experience-far approaches as not applicable to many contexts. The choice of experience-near or experience-far communication is not just a simple communication choice but rather it is a reflection of deeper mindsets about credibility. These mindsets must be confronted and questioned in order to generate sustainable linkages between academic knowledge and practitioner knowledge. The growing numbers of self-identified scholar-practitioners could contribute to this mindset shift through their work actively translating across the divide.

CONCLUSION

In this chapter we have revisited change implementation and change process theories to examine recent research,

including identifying several new areas of focus that show robust interest among practitioners. We have also identified several key challenges that limit continued development of the field and inhibit the movement of insight between academic and practitioner. Some of these challenges are new; some apparently promising directions of several years ago (such as a “top-tier” bridge journal) have not continued. They represent very strong challenges. At the same time, however, we have identified some contemporary currents that foster more bridging between academic scholarship and practice. These suggest optimism that there is still considerable desire that such bridging be accomplished. They also suggest some creative ways that were not present when we first wrote this chapter (e.g., *Evidence-Based Management*, a new journal with intentional bridging purposes).

We believe that change process theories and implementation theories, potentially, at least, offer a lot to each other. As we noted in 2003, how much they can be helpful to each other has not yet been fully realized. But the possibilities, the incipient seeds of their joint contribution, are alive and well.

WORK GROUPS AND TEAMS IN ORGANIZATIONS: REVIEW UPDATE

The latter part of the 20th, and the beginning of the 21st, centuries have witnessed a remarkable transformation of organizational structures worldwide. Ongoing economic, strategic, and technological imperatives are driving this transformation, with one of its more compelling aspects being the shift from work organized around individual jobs to team-based work structures (Lawler, Mohrman, & Ledford, 1995). Increasing global competition, consolidation, and innovation create pressures that are influencing the emergence of teams as the core building blocks of organizations. These pressures drive a need for diverse skills, expertise, and experience. They necessitate more rapid, flexible, and adaptive responses. They create a press for creativity, invention, and innovation. Teams enable these characteristics. In addition, organizations have globalized operations through expansion, mergers and acquisitions, and joint ventures placing increased importance on cross-cultural and mixed culture teams.

Steve W. J. Kozlowski gratefully acknowledges the Office of Naval Research (ONR), Command Decision Making Program (N00014-09-1-0519, S.W.J. Kozlowski and G. T. Chao, Principal Investigators), and the National Aeronautics and Space Administration (NASA, NNX09AK47G, S.W.J. Kozlowski, Principal Investigator) for support that, in part, assisted the composition of this chapter. Any opinions, findings, and conclusions or recommendations expressed are those of the authors and do not necessarily reflect the views of ONR or NASA.

Advanced computer and communication technologies provide new tools to better link individuals with their team and enable teams to be *virtual*—distributed in time and space—across the globe.

This ongoing transformation in the basic organization of work has captured the attention of researchers and is reflected by an expansion of theories addressing team functioning, an exploding number of empirical studies, and numerous literature reviews written on the burgeoning research focused on work teams. It is also reflected in a shift in the locus of team research. For most of its history, research on small groups has been centered in social psychology (McGrath, 1997). However, group and team research has migrated substantially to the fields of organizational psychology and organizational behavior. Indeed, Levine and Moreland (1990) in their extensive review of small group research concluded that, “Groups are alive and well, but living elsewhere. . . . The torch has been passed to (or, more accurately, picked up by) colleagues in other disciplines, particularly organizational psychology” (p. 620).

We began our previous review by documenting other review efforts that had published during the late 1980s and 1990s. Since that review (Kozlowski & Bell, 2003), research and theory development focused on team effectiveness have exploded across the allied fields of organizational psychology, organizational behavior, and human resource management. We provide a sampling of exemplar contributions in Table 17.1 to provide the reader with some sense of how this field of inquiry has evolved.

TABLE 17.1 Exemplar Reviews and Focused Models Addressing Aspects of Team Effectiveness

Year	Author(s)	Focus
1987	Goodman, Ravlin, & Schminke	Team task and technology—review
1987	Hackman	Normative model of team design
1987	Shea & Guzzo	Groups as human resources
1990	Sundstrom, De Meuse, & Futrell	Organization systems perspective
1991	Bettenhausen	Task-driven processes in teams—review
1991	McGrath	Groups—time, interaction, and performance
1992	Guzzo & Shea	Team research in organizations—review
1992	Hackman	Groups as a context for individual behavior
1993	Argote & McGrath	Group processes in organizations
1995	Ilgen, Major, Hollenbeck, & Segó	Team decision making
1996	Guzzo & Dickson	Team research in organizations—review
1996	Kozlowski, Gully, McHugh, Salas, & Cannon-Bowers	Leadership, team development, and adaptation
1997	Cohen & Bailey	Team research in organizations—field research
1997	Hinsz, Tindale, & Vollrath	Groups as information processors
1998	Cannon-Bowers & Salas	Team decision making under stress
1999	Devine, Clayton, Phillips, Dunford, & Melner	Teams in organizations—review
1999	Kozlowski, Gully, Nason, & Smith	Multilevel team development and adaptation
2000	Arrow, McGrath, & Berdahl	Groups as complex systems
2000	Gully	Team effectiveness since 1985—review
2000	Sundstrom, McIntyre, Halfhill, & Richards	Team research in organizations—review
2002	B. S. Bell & Kozlowski	Typology of virtual teams—leadership
2003	Kozlowski & Bell	Team effectiveness—review
2004	Kerr & Tindale	Group-decision-making research—review
2004	Salas, Stagl, & Burke	25 years of team effectiveness research—review
2005	Ilgen, Hollenbeck, Johnson, & Jundt	Team effectiveness review—IPO to IMO—review
2005	Kirkman & Mathieu	Team virtuality
2005	Mannix & Neale	Team diversity—review
2006	Kozlowski & Ilgen	Team effectiveness—50 years of theory, research, and applications—review
2007	Edmondson, Dillon, & Roloff	Team learning—review
2008	Kozlowski & Bell	Team learning
2008	Mathieu, Maynard, Rapp, & Gilson	Team effectiveness—1997–2007—review
2010	Fiore, Rosen, Smith-Jentsch, Salas, Letsky, & Warner	Macro-cognition in teams
2010	Hackman & Katz	Group behavior and performance—review
2011	B. S. Bell & Kozlowski	Team errors
2011	Cannon-Bowers & Bowers	Team development and functioning—review
2011	Jackson & Joshi	Team diversity—review
2011	Zaccaro, Marks, & DeChurch	Multiteam systems
2012	B. S. Bell, Kozlowski, & Blawath	Team learning—integration and review
2012	Chen & Tesluk	Team participation and empowerment—review
2012	Hollenbeck & Spitzmuller	Team structure
2012	Kirkman, Gibson, & Kim	Virtual teams—review
2012	Mathieu & Gilson	Team effectiveness criteria—review

An abbreviated tour through the research highlighted in Table 17.1 is informative. Much of the initial scholarship was focused on characterizing the differences brought to group and team research by taking an organizational perspective. For example, Goodman, Ravlin, and Schminke (1987) highlighted one of the key distinctions between the small-group literature, which pays relatively little attention to the group task and its technology, and the organizational literature, which views *what groups do* and *how they do it* as critical characteristics. Similarly,

Bettenhausen (1991) documented the emphasis in organizational research on task-driven processes in teams, relative to the small-group focus on interpersonal attraction and interaction. Sufficient primary research began to amass such that extensive and focused reviews of the literature were introduced (e.g., Cohen & Bailey, 1997; Devine, Clayton, Phillips, Dunford, & Melner, 1999; Gully, 2000; Guzzo & Dickson, 1996; Shea & Guzzo, 1987). As the shift in locus to “teams in organizations matured,” more topic-specific theory and research

focused, for example, on virtual teams, leadership, and decision making began to appear. Since our prior review in 2003, the field of team effectiveness theory and research has continued to expand its scope and depth with topics focusing on, for example, team diversity, multi-team systems, team learning, and macrocognition. An examination of this body of work leads to the conclusion that there is an enormous wealth of actionable knowledge available to enhance the effectiveness of work teams in organizations (Kozlowski & Ilgen, 2006). Nevertheless, the answers to many fundamental questions remain under-researched and elusive.

Our objective in this chapter is to provide an integrative perspective on work groups and teams in organizations, one that addresses primary foci of theory and research, highlights applied implications, and identifies key issues in need of research attention and resolution. Given the volume of existing reviews, our review is not designed to be exhaustive. It updates our 2003 review, using representative work and meta-analytic findings to characterize key topics, and focusing on recent work that breaks new ground to help move theory and research forward (see Kozlowski & Bell, 2003; Kozlowski & Ilgen, 2006). We believe that there is much value in taking an integrative view of the important areas of team research, identifying key research themes, and linking the themes and disparate topics closer together. To the extent that we identify new and necessary areas of theory development and research, the value of this approach will be evident.

The chapter organization and review focus is illustrated in Figure 17.1. We begin by examining the nature of work

teams. We define them, identify four critical conceptual issues—*context*, *workflow*, *levels*, and *time*—that serve as review themes, and discuss the multitude of forms that teams may assume. We then shift attention to the heart of the review, examining key aspects of the creation, development, operation, and management of work teams. To accomplish our objectives of breadth and integration, we adopt a *life-cycle perspective* to organize the review. Teams are not actually studied this way, but the life-cycle perspective provides an integrative framework that highlights important topic areas—many that are under-studied. Topics involved in the team life cycle include: (a) team composition; (b) team formation, socialization, and development; (c) team processes, effectiveness, and enhancements; (d) team leadership and motivation; (e) and team continuance and decline. We characterize representative theory and research, identify thematic limitations, and highlight work that is beginning to push the boundaries on our critical conceptual issues. We also address application concerns where possible. Finally, we close with a discussion that reflects back on the topics, considers the state of progress regarding our critical conceptual themes, and suggests directions for new research to foster continued progress and development.

THE NATURE OF WORK TEAMS AND GROUPS

What Is a Team?

Although some scholars distinguish work teams and work groups (Katzenbach & Smith, 1993), we make no such

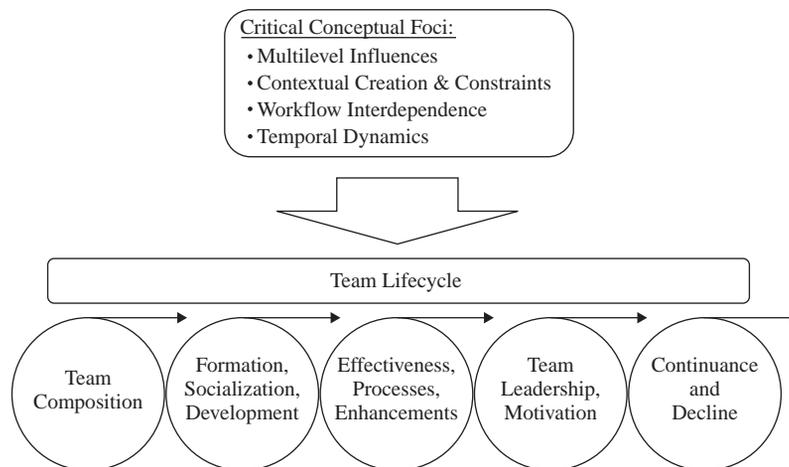

Figure 17.1 Review conceptual foci and team life cycle

Copyright © S. W. J. Kozlowski & B. S. Bell, 2011. All rights reserved worldwide. Used with permission.

distinction and use the terms interchangeably. Others distinguish dyads or triads from larger teams. Although we acknowledge that intrateam processes increase in complexity with more team members, we do not highlight these distinctions in this chapter. Work teams and groups come in a variety of types and sizes, cutting across different contexts, functions, internal processes, and external linkages. However, several features provide a foundation for a basic definition. Work teams and groups: (a) are composed of two or more individuals, (b) who exist to perform organizationally relevant tasks, (c) share one or more common goals, (d) exhibit task interdependencies (i.e., workflow, goals, knowledge, and outcomes), (e) interact socially (face-to-face or, increasingly, virtually), (f) maintain and manage boundaries, and (g) are embedded in an organizational context that sets boundaries, constrains the team, and influences exchanges with other units in the broader entity (Arrow, McGrath, & Berdahl, 2000; Hackman, 1987; Kozlowski, Gully, Nason, & Smith, 1999; Kozlowski & Bell, 2003; Salas, Dickinson, Converse, & Tannenbaum, 1992).

Critical Conceptual Foci

We view teams from an organizational systems perspective. They are embedded in an open yet bounded system composed of multiple, nested levels. This broader system sets *top-down* constraints on team functioning. Simultaneously, team responses are complex *bottom-up* phenomena that emerge over time from individual cognition, affect, behavior, and interactions among members within the team context (Kozlowski & Klein, 2000). Based on this perspective, we assert that four conceptual issues are critical in efforts to investigate and understand work teams: (a) multilevel influences, (b) contextual constraint and creation, (c) task or workflow interdependence, and (d) temporal dynamics. We briefly introduce these conceptual foci below and use them as review themes to identify both the strengths and limitations of extant research.

Multilevel Influences

As our definition makes clear, organizations, teams, and individuals are bound together in a multilevel system. Teams don't behave, individuals do; but they do so in ways that create team-level phenomena. Individuals are nested within teams, and teams in turn are linked to and nested in a larger multilevel system. This hierarchical nesting and coupling, which is characteristic of organizational systems, necessitates the use of multiple levels—individual, team, and the higher level context—in efforts

to understand and investigate team phenomena. However, many of the theoretical, measurement, and data analytic issues relevant to a multilevel perspective on teams are often neglected in research and practice. These issues are especially important when researchers try to attribute individual characteristics to the team collective (e.g., team ability, team personality, team learning). Such generalizations necessitate precise multilevel theory and analyses to ensure meaningfulness (i.e., construct validity) of the collective team-level constructs (Kozlowski & Klein, 2000). Unfortunately, there are many examples of such generalizations that lack the standing of true constructs.

Contextual Constraint and Creation

Teams are embedded in an organizational context and the team itself enacts a context for team members (Hackman, 1992). The broader organizational context characterized by technology, structure, leadership, culture, and climate constrains teams and influences their responses. However, teams also represent a proximal context for the individuals who compose them. Team members operate in a bounded interactive context that they in part create by virtue of their attributes, interactions, and responses. Team-level normative expectations, shared perceptions, and compatible knowledge are generated by and emerge from individual interactions. Dynamic team processes in part create contextual structure that constrains subsequent team processes. Thus, the team context is a joint product of both top-down and bottom-up influences.

Workflow Interdependence

The centrality of workflow interdependence is one issue that clearly distinguishes the work teams and small-group literatures (Goodman et al., 1987). In the organizational literature, *technology*, and the tasks it entails, denotes the means by which system inputs are transformed or converted to outputs; technology is not equipment or support systems (e.g., McGrath & Hollingshead, 1994). Technology and its associated tasks create a structure that determines the flow of work and linkage across team members. Interactions among work team members are substantially influenced by this workflow structure (Steiner, 1972; Van de Ven, Delbecq, & Koenig, 1976), which links individual inputs, outcomes, and goals. Thus, it has a critical influence on team processes essential to team effectiveness. In contrast, laboratory tasks in small-group research are often pooled or additive, thereby minimizing the necessity for task-driven interaction among team members (McGrath, 1997). From an organizational systems perspective, the task workflow sets interaction

requirements and constraints that must be considered in team theory, research, and practice.

Temporal Dynamics

Finally, time is an important characteristic of work teams (McGrath, 1990). Teams have a developmental lifespan; they form, mature, and evolve over time (Morgan, Salas, & Glickman, 1993). Team constructs and phenomena are not static. Many, indeed, most team-level phenomena (e.g., collective efficacy, mental models, performance) emerge upwards from the individual to the team level and unfold via complex temporal dynamics (Kozlowski et al., 1999) that include not only linear, but also cyclical and episodic aspects (Kozlowski, Gully, McHugh, et al., 1996; Marks, Mathieu, & Zaccaro, 2001). Although time is explicitly recognized in models of team development, it is largely neglected in many other areas of team research; yet time is relevant to virtually all team phenomena. It is impossible to understand team effectiveness without paying attention to the processes that unfold over time to yield it (Mohammed, Hamilton, & Lim, 2009).

Types of Work Teams

Work teams can assume a wide variety of different forms—they are not unitary entities. Many factors or contingencies relevant to effective team functioning vary across different types of teams, creating challenges for studying and understanding them. This fact is reflected in the many efforts to describe, classify, or otherwise distinguish differences among teams. We consider some of the major distinctions below and then comment on their theoretical and research value.

General Typologies

General typologies are an effort to distinguish a broad range of team types. For example, Sundstrom, McIntyre, Halfhill, and Richards (2000) integrated the Sundstrom, DeMeuse, and Futrell (1990) and Cohen and Bailey (1997) typologies to yield six team categories: (a) production, (b) service, (c) management, (d) project, (e) action and performing, and (f) advisory. Production teams represent core employees who cyclically produce tangible products (e.g., automobile assembly) and vary on discretion from supervisor-led to semi-autonomous to self-directed. Service teams engage in repeated transactions with customers (e.g., airline attendants) who have different needs, making the nature of the transactions variable. Senior managers of meaningful business units with primary responsibility for directing and

coordinating lower level units under their authority comprise management teams. Project teams are temporary entities that execute specialized time-constrained tasks and then disband (e.g., new product development). Action and performing teams are composed of interdependent experts who engage in complex time-constrained performance events. Examples include aircrews, surgical teams, military units, and musicians.

More Specific Classifications

In addition to general typologies, researchers have identified more specific types of teams. For example, some scholars have distinguished crews from other types of work teams (e.g., Cannon-Bowers, Salas, & Blickensderfer, 1998). The key distinguishing characteristic is the capability and necessity for crews to form and be immediately prepared to perform together effectively (Ginnett, 1993). Thus, advocates of this distinction assert that crews, unlike more conventional teams, do not go through an identifiable developmental process (Arrow, 1998). Examples include aircrews, military combat units, and surgical teams. However, it is notable that crews are used for team tasks that necessitate high expertise, extensive training, and well-developed, standardized performance guidelines. Thus, while crews continually form, disband, and reform with new members as an integral part of their life cycle, the high level of prior socialization, trained knowledge, and explicit performance standards provide strong structural supports that substitute for an extended group development process.

Top management teams (TMT; Hambrick & Mason, 1984; Jackson, 1992a) represent another specific classification, one based on level in the organizational hierarchy. Because it is difficult to gain access to TMTs, much of the research on TMT effectiveness has focused on factors that can be gleaned through archival records. As a result, research has centered on TMT composition (e.g., heterogeneity of function; organizational tenure; team tenure, age, and education; team size) or its treatment as team diversity (e.g., Jackson, Joshi, & Ehardt, 2003) and the external environment (e.g., industry as a proxy for environmental turbulence, market characteristics), and their effects on organizational effectiveness (Eisenhardt & Schoonhoven, 1990; Finkelstein & Hambrick, 1990; Hambrick, Cho, & Chen, 1996; Simons, Pelled, & Smith, 1999; Smith et al., 1994; West & Anderson, 1996). Much of this research is in the strategic management literature or in specialty journals (e.g., information technology, software development). Although the amount of empirical work in this area is relatively small compared to work

team research in general, the area is active and growing. One troubling aspect of this growing area, however, is its relative independence of the broader work teams literature (Cohen & Bailey, 1997). Since our last review there is evidence that this has started to change, with some more recent research that has focused on TMT interdependence (Barrick, Bradley, Kristof-Brown, & Colbert, 2007; Carmeli & Schaubroeck, 2006), behavioral integration (Carmeli & Schaubroeck, 2006; Lubatkin, Simsek, Ling, & Veiga, 2006; Simsek, Veiga, Lubatkin, & Dino, 2005), cohesion and conflict (Michalisin, Karau, & Tangpong, 2004; Simons & Peterson, 2000), and shared leadership (Ensley, Hmieleski, & Pearce, 2006). Nonetheless, this continues to be a neglected issue in need of more directed rectification.

More recently, the globalization of organizations and changing nature of work have yielded new team forms such as distinctions based on culture—cross-cultural, mixed-culture, and transnational teams (Earley & Erez, 1997)—and collocation in time and space—virtual teams (B. S. Bell & Kozlowski, 2002; Kirkman, Gibson, & Kim, 2012). For example, the challenge of cross- and mixed-culture teams is to break through the barriers of different fundamental values, cultural assumptions, and stereotypes to successfully coordinate and jointly perform effectively. One of the biggest conceptual challenges in this area of work is dealing with the multiple levels—individual, group, organization, and culture—that are relevant to understanding such teams. Chao (2000), for example, presents a multilevel model of intercultural relationships that specifies how individual- and group-level interactions are affected by higher-level relationships. Essentially, interactions among individuals or groups of different cultures are affected by their cultural identities, and the relative standing of the cultures on factors important to the interaction. Variation in how groups deal with this higher-level linkage affects the quality of interaction and the potential for group effectiveness. Thus, Chao's model provides a basis to guide research on intercultural team interactions. Chao & Moon (2005) go further, developing a “meta-theory” of culture—the *cultural mosaic*—as an individual property composed by tiles of demographic, geographic, and associative differences. Different tiles of the mosaic can be activated by situational cues, serving either to connect culturally dissimilar team members across common tiles or to fracture them along faultlines.

B. S. Bell and Kozlowski (2002) distinguish virtual teams from conventional face-to-face teams based on two features: (a) spatial distance—virtual team members

are dispersed in space, and (b) technological mediation of information, data, and personal communication—virtual team members interact via advanced communications media. These two features enable diverse expertise—located worldwide—to be combined into a team that transcends the usual boundaries of space and time. As organizations and work continue to evolve, new types of work teams will be created and classified. Research on virtual teams has literally exploded since our prior review, pushed by needs for flexibility and diverse expertise, and enabled by advances in bandwidth. One key aspect of Bell and Kozlowski's typology was to advance an appreciation that virtual teams can exhibit a range of “virtuality,” rather than being a type of team (i.e., face-to-face vs. virtual). That perspective has become common in the research literature (Kirkman & Mathieu, 2005), with recent scholarship defining the degree of virtuality in terms of spatial distance, media usage, and cultural differences (Chen, Kirkman, Kim, Farh, & Tangirala, 2010; Gibson & Gibbs, 2006; Tsui, Nifadkar, & Ou, 2007). See Kirkman et al. (in press) for a comprehensive review of this burgeoning area of research and Mesmer-Magnus et al. (2011) for a meta-analytic investigation of the effects of virtuality on team information sharing.

The Role of Typology in Understanding Teams

Although there is value in characterizing distinctions across different types of teams, description and classification are merely the first steps in comprehending the implications of such differences for effective team functioning. In our view, it is more useful to focus on the dimensions that underlie apparent differences in team classifications or typologies. Surfacing such dimensions is critical to identifying the varying factors or contingencies that determine the effectiveness of different types of teams. Identifying these factors will better enable researchers and practitioners to specify design and operational factors that promote team effectiveness for different teams.

Some scholars have made steps in this direction. Sundstrom et al. (1990), for example, identified three dimensions underlying their typology: (a) work team differentiation—the degree to which membership is inclusive, variable, or exclusive and the span of the team's life cycle; (b) external integration—the degree to which the team's task is entrained by, that is, requires synchronization with, organizational paces external to the team; and (c) work cycles—the general length of the team's task and the degree to which performance episodes are multiple, variable, repeatable, and novel.

Kozlowski et al. (1999) focused directly on dimensions rather than classification, proposing that five features— (a) task, (b) goals, (c) roles, (d) process emphasis, and (e) performance demands—distinguish teams ranging along a simple-to-complex continuum. Complex teams are characterized by:

1. Tasks that are externally driven, dynamic, and structured by explicit workflows.
2. Common goals that necessitate specific individual contributions that may shift over a work cycle.
3. Roles that are specified and differentiated such that they require specialized knowledge and skill.
4. A process emphasis that focuses on task-based roles, task interaction, and performance coordination.
5. Performance demands that require coordinated individual performance in real-time, the capability to adapt to shifting goals and contingencies, and a capacity to continually improve over time.

In contrast, simple teams are characterized by:

1. Tasks that are internally oriented, static, and unstructured in that they lack explicit workflows.
2. Common goals that make no specific demands for individual contributions and that are fixed for the team’s life cycle.
3. Roles that are unspecified and undifferentiated, such that all team members possess essentially equivalent knowledge and skill.
4. A process emphasis that focuses on social roles, social interaction, normative behavior, and conflict.

5. Minimal performance demands that allow pooled or additive contributions to the group product.

Similarly, B. S. Bell and Kozlowski (2002) characterized a continuum of team complexity ranging from simple to complex based on the dimensions of: (1) task environment, (2) external coupling, (3) internal coupling, and (4) workflow interdependence. The complex end of the continuum, relative to the simple end, is defined by tasks that are dynamic as opposed to static, external coupling that is tight rather than loose, and internal coupling that is synchronous and strong in contrast to asynchronous and weak. Workflow interdependence ranges from complex to simple as: intensive, reciprocal, sequential, and pooled (see Van de Ven et al., 1976).

Integrating across the dimensions described previously, we believe the typology features illustrated in Figure 17.2 capture most of the unique characteristics that distinguish different team forms:

1. The external environment or organizational context in terms of its (a) dynamics and (b) degree of required coupling to the team.
2. Workflow interdependence with its implications for (a) role, (b) goal, and (c) process linkages.
3. Member (a) composition (ability, personality, values) (b) diversity (demographic, geographic, associational), (c) proximity (spatial distribution), and (d) stability (rotation/replacement rate).
4. Temporal characteristics that determine the nature of (a) performance episodes and cycles, (b) developmental progression, and (c) the team life cycle.

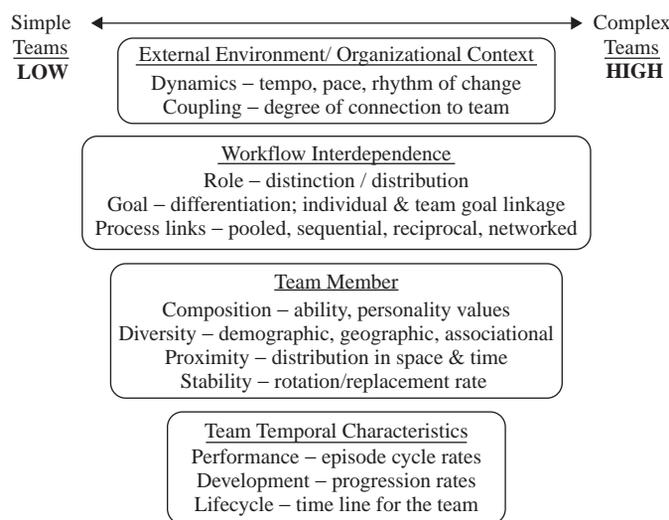

Figure 17.2 A typology of team complexity

We offer these features as a point of departure for a concerted effort to develop a definitive set of dimensions that characterize key contingencies essential for the effectiveness of different types of teams.

We believe that continuing efforts to better characterize dimensions that distinguish different types of teams can help pay big theoretical dividends. More to the point, we believe that focusing on typology and classification is misguided if viewed as an end in itself; there is the danger of reifying classifications and failing to see underlying factors that account for apparent differences. Rather, by surfacing dimensions that distinguish teams, we will be better equipped to identify the critical contingencies relevant to effectiveness for different types of teams. Understanding what factors constrain and influence effectiveness for different types of teams will enable theoretical progress and better targeted interventions. This issue currently represents a major gap in theory and research, and substantially limits our ability to develop meaningful applications and interventions designed to enhance team effectiveness.

TEAM COMPOSITION

Events within teams often reflect the number and type of people who are its members. As a result, considerable research has focused on team composition, or the nature and attributes of team members. Team composition is of research and practical interest because the combination of member attributes can have a powerful influence on team processes and outcomes. A better understanding of such effects will help practitioners to select and construct more effective teams (Hollenbeck, DeRue, & Guzzo, 2004).

Moreland and Levine (1992) categorized team composition research along three dimensions. First, different characteristics of a team and its members can be studied, including size, demographics, abilities and skills, and personalities. Second, the distribution of a given characteristic within a group can be assessed. Measures of central tendency and variability are typically used, but special configurations are sometimes measured as well. Third, different analytical perspectives can be taken toward the composition of a team. Team composition can be viewed as a *consequence* of various social or psychological processes (e.g., socialization), as a *context* that moderates or shapes other behavioral or social phenomena, or as a *cause* that influences team structure, dynamics, or performance.

We review and discuss team composition issues along each of these three dimensions. First, we provide a brief

review of research that has focused on different characteristics of teams and their members. Second, we discuss issues relating to levels of conceptualization and analysis in research on team composition. Finally, we discuss some practical implications that can emerge from a better understanding of team composition and its effects on team structure, dynamics, and performance.

Team Size

Researchers have offered recommendations concerning the best size for various types of teams. Katzenbach and Smith (1993) suggested that work teams should contain a dozen or so members, whereas Scharf (1989) suggested that seven was the best size. A variety of other such recommendations are easily found in the literature. Such recommendations are difficult to evaluate, because they are often based on personal experiences rather than empirical evidence. However, it is also difficult to determine what constitutes appropriate team size from empirical research. Some research suggests that size has a curvilinear relationship with effectiveness such that too few or too many members reduces performance (Nieva, Fleishman, & Reick, 1985), whereas other studies have found team size to be unrelated to performance (Hackman & Vidmar, 1970; Martz, Vogel, & Nunamaker, 1992) or that increasing team size actually improves performance without limit (Campion, Medsker, & Higgs, 1993).

These differing recommendations and results are likely due to the fact that appropriate team size is contingent on the task and the environment in which the team operates. For example, larger teams may have access to more resources, such as time, energy, money, and expertise, that may not only facilitate team performance on more difficult tasks but also can provide more “slack” if environmental conditions worsen (Hill, 1982). Consistent with these arguments, recent research has found that the size of creative teams in the artistic and scientific fields has grown significantly over time, which can be attributed, at least in part, to the fact that the tasks performed by these teams have become more complex and intricate with time (Guimerá, Uzzi, Spiro, & Amaral, 2005; Wuchty, Jones, & Uzzi, 2007). However, there is also evidence that team size may stabilize once an “optimal” size is reached (Guimerá et al., 2005), because as teams grow larger they become more likely to experience coordination problems that interfere with performance (e.g., Lantané, Williams, & Harkins, 1979) and motivation losses caused by a dispersion of responsibility (Sheppard, 1993). Yet, the question of the “optimal” group size is a complex one

and future research is needed to determine the impact of team size given specific team contingencies, such as the nature of the team task and its consequent internal and external coupling demands.

Diversity

The extent to which team processes and outcomes are influenced by the homogeneity or heterogeneity of team member characteristics has also been the focus of considerable attention, although it is difficult to determine whether team diversity is desirable. Studies have reported that diversity has positive (Bantel, 1994; Gladstein, 1984), negative (Haleblian & Finkelstein, 1993; Jackson et al., 1991; Pelled, Eisenhardt, & Xin, 1999; Wiersema & Bird, 1993), or even no effects on team effectiveness (Campion et al., 1993). In their review of this literature, Mannix and Neale (2005) conclude that social-category (i.e., surface-level) differences, such as race and gender, tend to have negative effects on the ability of groups to function effectively, whereas underlying (i.e., deep-level) differences, such as differences in functional background or personality, are more often positively related to team performance, but only when the group process is carefully controlled. However, they also argue that to disentangle the mixed effects of diversity in teams, future research needs to more carefully consider several issues. First, the approach used to categorize and measure diversity may have implications for our knowledge of the effects of diversity in teams. Multifaceted approaches that allow for an integrative view of the effects of multiple types of diversity may prove more informative than approaches that focus on a single attribute or restricted set of attributes. For example, research on group *faultlines* examines how the configuration of multiple member attributes can influence the formation and strength of subgroups, which in turn impact group dynamics (e.g., subgroup conflict) and performance (Lau & Murnighan, 1998; Thatcher & Patel, in press). In addition, Harrison and Klein (2007) argue that there are three fundamental types of diversity—separation, variety, and disparity—that differ in their meaning, shape, and consequences. Accordingly, researchers need to clearly specify which diversity types they are studying and to align them with appropriate operationalizations. Second, greater attention should be focused on understanding the contextual factors that moderate the effects of diversity. Past research suggests that the effects of diversity may depend on the organizational context (Kochan et al., 2003) and the nature of the team's tasks (Jackson, May, & Whitney, 1995). In addition, it is important to consider temporal issues, as

research suggests that the impact of diversity may vary across time. Watson, Kumar, and Michaelsen (1993), for example, found that homogeneous groups displayed better initial performance than heterogeneous groups, but these effects dissipated across time and heterogeneous groups later performed better than more homogeneous groups. Finally, research needs to decompose the effects of diversity in teams by measuring not only the group processes that explain diversity's effects (e.g., communication, conflict) but also the underlying psychological mechanisms (e.g., personal identity, attitude differences) that link diversity attributes to these processes (Mannix & Neale, 2005). For instance, the *cultural mosaic* framework presented by Chao and Moon (2005) draws upon identity theory to articulate how combinations or patterns of demographic, geographic (e.g., coastal/inland), and associative (e.g., politics) cultural tiles across members can connect to compose meaningful shared identities or fracture the group across faultlines.

Dispositions, Abilities, and Values

In addition to diversity, researchers have also considered team composition effects of constructs like personality and cognitive ability on team effectiveness. Unlike diversity, which is usually directly conceptualized and assessed as a team-level property (homogeneity–heterogeneity), personality and ability are fundamentally individual-level psychological characteristics. Such constructs necessitate models of emergence to guide conceptualization, measurement, and representation at the team level. Many potential representations are possible, including averages, highest or lowest, variance, and even complex configurations. In the absence of an explicit theoretical model of emergence to guide composition, “team personality” or “team ability” (or other such constructs) are of questionable construct validity and research may yield spurious findings (Kozlowski & Klein, 2000).

Personality

The growth of teams as the basic building blocks of organizations combined with renewed interest in personality in the mid-1990s has led researchers to examine the impact of team personality composition on team effectiveness. Although this research generally supports the link between aggregate team member personality and team performance, LePine, Buckman, Crawford, and Methot (2010, p. 2) note in a recent review of this literature that “findings from research on the relationship between team member personality and team effectiveness have not

accumulated in a manner that is easy to decipher.” This is due to the fact that researchers have focused on a variety of personality variables, have examined different criteria related to the effectiveness of teams, and have adopted different approaches to aggregating the personality of individual team members.

A meta-analysis by S. Bell (2007) revealed that the overall effects of team personality composition on team effectiveness were quite modest (conscientiousness, $\rho = 0.11$; agreeableness, $\rho = 0.12$; extraversion, $\rho = 0.09$; emotional stability, $\rho = 0.04$; openness to experience, $\rho = 0.05$). However, she also found that study setting was a strong moderator of the team personality composition and team performance relationships. The relationships were stronger in field settings (conscientiousness, $\rho = 0.30$; agreeableness, $\rho = 0.31$; extraversion, $\rho = 0.15$; emotional stability, $\rho = 0.06$; openness to experience, $\rho = 0.00$) compared to lab settings (conscientiousness, $\rho = 0.04$; agreeableness, $\rho = 0.03$; extraversion, $\rho = 0.06$; emotional stability, $\rho = 0.03$; openness to experience, $\rho = 0.20$). Bell also examined team composition operationalization (e.g., mean, maximum, minimum, heterogeneity, other) as a moderating factor and found that the strongest effects were observed in field settings when team personality composition was operationalized as the team mean, with the exception of agreeableness, which had an equally strong effect when operationalized as the team minimum.

A second meta-analysis conducted by Prewett, Walvord, Stilson, Rossi, and Brannick (2009) also found weak, but significant, overall relationships between mean personality composition and team performance. Further, the authors highlight several additional factors that may moderate this relationship. First, they provide some evidence that the effects of team personality composition may depend on the type of criteria that are examined. Specifically, they found that agreeableness, extraversion, and emotional stability had stronger relationships with team behaviors/processes than with team outcomes, but the 95% confidence intervals indicated this difference was significant only in the case of extraversion. Although this finding suggests that team personality may influence team performance through its effects on team-level processes, LePine et al. (2010) note that very little research to date has directly assessed this mediated relationship. Second, Prewett et al. provide support for the notion that team personality composition has stronger effects on team performance when tasks require high team interdependence. For instance, stronger effects for mean personality composition were observed in intensive workflow patterns

than in pooled workflow patterns, although the difference was only statistically significant in the case of agreeableness. Finally, they provide some evidence for both task-based and trait-based approaches to aggregation, although the findings were mixed and the results suggest that the mean level of a personality trait in a team tends to be a more consistent and stronger predictor of team outcomes than the minimum, maximum, or variance (LePine et al., 2010). Overall, it is clear that personality composition has important implications for team effectiveness, although the mechanisms by which team personality composition influences team performance and the factors that moderate the effects of team personality require further investigation.

Cognitive Ability

Among the factors studied in relation to work team effectiveness, one consistent predictor is team members' collective cognitive ability. Team members' average cognitive ability is related to team performance among military tank crews (Tziner & Eden, 1985), assembly and maintenance teams (Barrick, Stewart, Neubert, & Mount, 1998), and service teams (Neuman & Wright, 1999). In addition, LePine, Hollenbeck, Ilgen, and Hedlund (1997) found that the performance of hierarchical decision-making teams was enhanced when both the leader and staff were high in cognitive ability and LePine (2005) found that teams comprising members of higher cognitive ability were better able to adapt their role structure to an unexpected change in the task context.

A meta-analysis by Devine and Phillips (2001) found a positive relationship between average team cognitive ability and team performance ($r = 0.29$). The strength of the ability-performance relationship differed somewhat when the lowest member score was used ($r = 0.25$) or when the highest member score was utilized ($r = 0.21$), but the confidence intervals for the three different operational definitions (mean, low, high) overlapped, suggesting that none is clearly superior. However, the standard deviation index of team cognitive ability exhibited a very weak and negative relationship with team performance ($r = -0.03$) and the confidence interval included zero, which suggests that there may be no relationship between the dispersion of team members' cognitive ability and team effectiveness. They also examined study setting as a potential moderator of the relationship between average team cognitive ability and team performance, and found that the relationship was considerably stronger in lab studies ($r = 0.37$) than field studies ($r = 0.14$). S. Bell (2007) found a similar positive relationship between average team cognitive

ability and team performance ($\rho = 0.31$) and also found that this estimate differed only slightly when the lowest member score was used ($\rho = 0.34$) or the highest member score was utilized ($\rho = 0.27$). In contrast to the earlier meta-analysis, however, she found that the effect of average team cognitive ability on team performance was similar in both lab and field settings. Finally, S. Bell (2007) found that team cognitive ability was related to team performance in both physical and intellectual teams. Thus, although research in this area is promising, continued work is needed to identify those conditions under which team-level cognitive ability has more or less of an impact on team performance.

Values

Although the majority of research on team composition has focused on personality and ability, there is an emerging literature that examines the relationship between values and team performance. Values represent beliefs about desirable behaviors that transcend specific situations and are relatively enduring over time. Most studies that have investigated the values and team performance relationship have done so in terms of team member collective orientation and preference for teamwork. For example, a recent study by Randall, Resick, and DeChurch (2011) found that teams with higher average levels of psychological collectivism engaged in greater information sharing during a decision-making simulation. Jung, Sosik, and Baik (2002) examined the relationship between preference for teamwork and the performance of American and Korean student teams on two projects—one collected at the middle of the semester and one collected at the end. They found that preference for teamwork did not influence performance at the first time period, but at the second time period it was negatively related to performance among the Koreans and positively related to performance among the Americans. In her meta-analysis, S. Bell (2007) found that both collectivism ($\rho = 0.25$) and preference for teamwork ($\rho = 0.18$) were positively related to team performance. The value–performance relationships were stronger in field settings (collectivism, $\rho = 0.35$; preference for teamwork, $\rho = 0.22$) than in lab settings (collectivism, $\rho = 0.00$; preference for teamwork, $\rho = 0.01$). Overall, these findings provide preliminary evidence that certain values, such as collectivism and preference for teamwork, are important for team performance. Future research should broaden the view of values that are considered and also explore how the relationship between values and team effectiveness evolves over time and is shaped by aspects of the context (e.g., culture) in which the team is embedded.

Theoretical and Empirical Issues

Levels of conceptualization, measurement, and analysis have tended to be either ignored or treated simply in much of the research on team composition. The dominant use of averaging or additive models to guide the aggregation of individual characteristics to the team level suggests the use of simple team tasks or a very limited conceptualization of the compositional construct at the higher level (Kozlowski & Klein, 2000). Such issues are critical for developing a sound understanding of how team member attributes combine to form higher-level constructs and must be carefully articulated. Well-defined models of emergence need to guide the representation of individual-level characteristics at the team level. Kozlowski and Klein (2000) provide a differentiated typology of six different emergent processes, based on contextual constraints and interaction processes, for how lower-level phenomena manifest at higher levels. Such models can assist researchers in determining the most appropriate method for representing lower-level phenomena at higher levels. For example, when emergence is more continuous and linear, averaged or summed values are an appropriate method of representing lower-level phenomena at the team level. However, when emergence is more discontinuous and nonlinear, it is more appropriate to use dispersion or configural models to capture the emergent characteristic of the team. For example, conceptualizing team composition as a pattern of different but compatible personalities represents the use of a configural model (e.g., Stewart & Barrick, 2004).

There has also been a relative lack of attention to the latent constructs that underlie variables of interest within research on team composition. As a result, it is often difficult to determine precisely how or why variables such as team member age, tenure, or demographics influence team processes and outcomes. Recent research on team personality and cognitive ability composition has placed greater attention on understanding these underlying constructs; however, additional research is needed to identify the mechanisms by which team composition has its effects.

Applied Issues

An understanding of team composition can serve as a valuable tool for selecting and constructing effective teams. Procedures could be designed to produce the optimal blend of employee characteristics (Driskell, Hogan, & Salas, 1987; Heslin, 1964; Jackson, 1992b) including

hiring new workers or firing old ones, training current workers, or engaging the services of adjunct workers, such as temporary employees or consultants (Klimoski & Jones, 1995; Moreland, Argote, Krishnan, 1998; Stevens & Campion, 1994).

Although past work provides some valuable information about how to manage team composition, researchers have often adopted a “more is better” approach (i.e., the additive model assumption), suggesting that the person with the highest score on a particular attribute (e.g., cognitive ability) or the most skilled individual should be selected for the team. However, recent research suggests that it may be more important to create an appropriate configuration of team member characteristics. For example, a recent study by Goncalo, Flynn, and Kim (2010) found that the presence of more narcissistic individuals facilitated the creativity of the group process and product, but only up to a point, at which adding more narcissistic individuals begins to diminish group creativity. Similarly, research by Stewart and Barrick (2004) suggests that if a team consists of a lot of extraverts, it may be better to hire a less extraverted person or even an introvert. Conversely, if a team has no extraverts, it may be important to hire highly extraverted applicants. To create an appropriate blend of team member characteristics, one will need to know what personality traits currently compose the team and the target team personality configuration before selecting a particular individual. It may also be important to consider the team’s task, because it may be important to have a homogeneous group of team members for some types of tasks and a heterogeneous team composition for others (Neuman & Wright, 1999).

Human resource systems such as selection, training, and performance appraisal must be conceptualized and managed at the team level (Schneider, Smith, & Sipe, 2000) to appropriately address composition issues. Focusing on the individual level alone will not provide the information needed to make effective decisions regarding team composition. Including the team level provides information concerning not only the team’s current composition but also the team’s tasks and processes that assist in the development of an appropriate combination of team member characteristics for the task at hand. Recent work has proposed a multilevel model of human capital creation that describes how unit-level human capital resources emerge from individuals’ knowledge, skills, abilities, and other characteristics (Ployhart & Moliterno, 2011). Although more work is needed to elaborate and test the processes articulated within the model, it can help guide future research that examines how human resource

management systems, policies, and practices can be used to leverage composition toward higher levels of team effectiveness.

TEAM FORMATION, SOCIALIZATION, AND DEVELOPMENT

Formation

Teams may be formed anew, where all members are new to each other and the team. Or teams with a developmental history may have influxes and outflows of members that affect its composition and character. In either instance, team development and newcomer socialization to the team are relevant issues. Socialization has generally been seen as a mechanism for bringing new members into existing teams or groups. With few exceptions, much of this theory and research has focused on the socialization of individuals into the organization and, while theoretically relevant, has paid relatively little attention to the work group or team as central to the socialization process. That is, the vast majority of work on socialization in work settings focuses on organizational influences but is far less sensitive to the proximal social and work context within which socialization actually takes place. Thus, although socialization is a critical aspect of team maintenance and continuance, we know relatively little about it in the team context.

Team development tends to assume the formation of a brand new team with no prior history. Much of the classic theory in this area also assumes no broader organizational context, work roles, or prescribed interactions. Consider, for example, Tuckman’s (1965) classic model of group development, with its sequential stages of forming, storming, norming, and performing. Clinical, therapy groups, and training or “T-groups”—which provided the foundation for this model—have no prior history, no broader context, and are almost completely unstructured save for a common goal: to “get better.” Thus, the dominant focus in Tuckman’s model is on the group’s struggle to create structure to regulate their interpersonal interactions and to finally make progress toward the goal. Although this model—and the many, many others based on it—provides a useful contribution to our understanding of group development for simple teams, it provides little theoretical insight on skill development for work groups in organizations. As discussed in the prior section, work teams are subject to a variety of structural features that drive interactions and exchanges among members.

Interpersonal issues are relevant, but they do not dominate the developmental process. Yet, with few exceptions (Gersick, 1988; Kozlowski et al., 1999; McGrath, 1990; Morgan et al., 1993), there are relatively few theories that are specifically targeted on work team development.

Socialization

Existing teams are governed by a relatively stable set of norms, role expectations, and shared systems of knowledge and meaning (e.g., team climate, shared mental models). These informal structures emerge through social and work-based interactions among members across a group's developmental history. Newcomers present a potential challenge to this stable structure and are thus subject to efforts by team members to assimilate the person to it. At the same time, newcomers are confronted by a novel and ambiguous social and work context. While they want very much to "fit in" and "learn the ropes" and are generally prepared to accept guidance from the team, they may also seek to have the team accommodate to their needs, values, and capabilities. Thus, work team socialization is a process of mutual influence in which newcomers attempt to reduce uncertainty by learning about the work and team context, guided by team members who facilitate assimilation to existing norms, expectations, and meaning systems, while at the same time newcomers attempt to exert influence on the team to accommodate to their unique attributes and needs (Anderson & Thomas, 1996; Moreland & Levine, 1982).

Interestingly, even though researchers clearly recognize the centrality of the work group in the socialization process, the dominant perspective in the literature is characterized by a focus on *organizational* socialization—not on a primary process of *work group or team* socialization that occurs within a broader and more distal organizational context (Chao, Kozlowski, Major, & Gardner, 1994). Virtually all efforts to identify the relevant content of newcomer socialization make provision for learning about the work group and its social structure (e.g., Chao, O'Leary-Kelly, Wolf, Klein, & Gardner, 1994; Morrison, 1993; Ostroff & Kozlowski, 1992), but it is merely one part of a broader process. Moreover, early theory and research on organizational socialization can be characterized as accentuating the powerful influence that the organizational context exerted on newcomers in an effort to assimilate them. This was later followed by a shift in perspective that emphasized the proactive role that newcomers play in shaping their own socialization process. What has been largely missing is the sense of mutual influence as the

group seeks to assimilate the newcomer, and the newcomer endeavors to adapt while seeking accommodation by the group. This is a major shortcoming of the socialization literature, and means that our knowledge of the team socialization process is limited. There are, however, some notable exceptions.

Group and Team Socialization

Moreland and Levine (1982) detail a model of group socialization that focuses on membership processes, primarily applicable to autonomous voluntary groups who control their own membership and are not nested in a broader organizational context. Moreland and Levine (2001) extend the model to work group socialization, although its primary mechanisms are essentially the same. The major focus of the model is on mutual decisions on the part of a newcomer and the group regarding joining, assimilation and accommodation, and continuance or withdrawal of membership. The model spans five phases: investigation, socialization, maintenance, resocialization, and remembrance. Difficulties in assimilation or accommodation may prompt the group to resocialize a newcomer. Resocialization failure leads to lower commitment and exit. Aspects of the model are potentially relevant to team socialization—in particular, its explicit attention to the group as the primary locus of socialization and mutual expectations as drivers of the process. Remarkably, although the model has been elaborated in several papers, it has generated relatively little research attention and the little research that has been conducted has been limited to ad-hoc laboratory groups. Thus, the utility of the model to work team socialization remains to be established.

Based on a focused review of the organizational socialization literature, Anderson and Thomas (1996) present a model that is explicitly focused on work group socialization and the mutual influence of the newcomer and the group on outcomes of the process. Thus, it is an effort to address the neglected issues noted above. The model spans the socialization phases of anticipation, encounter, and adjustment, identifying potential characteristics of the newcomer and the group that may contribute to socialization as a process of mutual influence and adjustment. To date, the model has prompted several research efforts, which have provided support for the mutual influence of the newcomer and the group on the process of work group socialization (e.g., Chen & Klimoski, 2003).

Direct Findings for Work Team Socialization

Although most socialization research has neglected explicit attention to the role of the work group, there

are some exceptions; additionally, useful knowledge regarding team socialization can be gleaned from existing research. For example, as one aspect of their study, Chao, Kozlowski et al. (1994a) focused on how the quality of newcomer role development relations with their leader and team influenced role outcomes of ambiguity and conflict, with the role outcomes in turn expected to influence socialization effectiveness. Results indicated that newcomer role development quality predicted role outcomes. Moreover, role outcomes were better predictors of socialization effectiveness than organizational tactics, especially over time. Chao, Kozlowski et al. concluded that these findings supported the primacy of the work group, not the organization, as the locus of socialization.

Similarly, Major, Kozlowski, Chao, and Gardner (1995) examined the potential effects of leader and team relations on ameliorating the negative effects of unmet newcomer expectations on socialization outcomes. “Reality shock” is one of the major challenges for newcomers as they confront the unpleasant fact that their work expectations are largely unmet. An inability to resolve reality shock yields low commitment and satisfaction, and generally leads to withdrawal. Major et al. reasoned that positive relationships with the leader and work group members would moderate the effects of reality shock, weakening its relationship with negative outcomes. They reported support for their propositions, and concluded that high-quality interactions with the group leader and team members provided important supports for effective socialization into the work group.

Perhaps the best direct research examining team socialization is represented in two articles by Chen and Klimoski (2003) and Chen (2005) that offer differing, but complementary, insights on the process from the same data collection. They collected data from 70 newcomers, their team leaders, and 102 teammates in 3 sampling phases spanning 2 months. In the initial analysis, Chen and Klimoski based their theorizing on Pygmalion and Galatea effects (Eden, 1990). They reasoned that high team expectations for the newcomer would prompt the newcomer to be motivated to meet those expectations (the Pygmalion effect), which would also raise the newcomer’s self-expectations, confidence, intrinsic motivation, and effort—thereby fulfilling the newcomers’ own self-prophecy (the Galatea effect). Although this is a simplification of the model they evaluated, Chen and Klimoski essentially found that high expectations by the team and the newcomer prompted better newcomer role performance consistent with their theorizing. Chen went beyond this focus to examine a multilevel model of

newcomer adaptation that examined how newcomer performance and its improvement over time contributed to improvements in team performance. This second analysis is useful because it shows how newcomers “come up to speed” and begin to contribute to team effectiveness. It is unfortunate that there is not more research like this focused on team socialization processes over time.

Indirect Findings for Work Team Socialization

Results from research on socialization practices indicate that newcomers view supervisors and work group members as available and helpful socialization agents who are far more helpful than formal socialization practices (Louis, Posner, & Powell, 1983). Research on newcomer information acquisition also indicates the importance of work group members in the process of learning, sense making, and adjustment. Ostroff and Kozlowski (1992) hypothesized that newcomers have to resolve issues of their fit in the work group before they can turn attention to task and role issues. In support, they reported that newcomers focused on acquiring group knowledge early on, later shifting to task and role issues. Organizational factors were of lowest priority. They also found that supervisors and social learning in the group context were the most effective newcomer strategies for learning about the role and group. Perhaps most important, they reported that increasing newcomer reliance on the supervisor over time as a source of information was related to increases in newcomer satisfaction, commitment, and adjustment over time.

Role of the Team in Socialization

The research reviewed above clearly indicates that group leaders and members are key players in newcomer socialization. Unfortunately, however, this research provides little insight about group characteristics and their precise role in the socialization process. Moreland and Levine (1989) provide several suggestions in this regard. For example, they suggest that groups with a longer developmental history present a more difficult socialization challenge to the newcomer, because such groups will demand more assimilation and will resist accommodation efforts. There is some support for this notion. Katz (1982) reported that younger R&D groups communicated more with outsiders and were more open to new ideas; older groups were more insular. Similarly, groups that are typified by stable membership present a more difficult socialization environment relative to groups with frequent personnel inflows and outflows. And, groups that are more successful are more likely to be insular, whereas groups

experiencing performance problems may be more open to suggestions from newcomers with requisite knowledge and abilities. Groups can also apply deliberate socialization tactics. By controlling recruitment and selection they can influence the quality of fit, thereby aiding assimilation. By “encapsulating” the newcomer—maximizing their time and energy commitment to the group—they tie the newcomer to the group, minimizing alternative commitments and enhancing socialization. There is, however, little solid support for the effectiveness of these tactics in realistic team situations. More theory and research are clearly needed on *work team socialization*.

Development

Classic Stage Models

Several models describe the developmental stages groups pass through over their life span. The descriptive characteristics of these models are remarkably parallel to Tuckman’s (1965) widely cited model of group

development (Kozlowski et al., 1999; see Table 17.2). Tuckman reviewed the group literature, defined by therapy, T-group, natural, and laboratory group studies, and proposed that groups go through the developmental stages of *forming, storming, norming, and performing*.

As team members first come together during the formation stage, they cautiously begin to explore the group and attempt to establish some social structure. They attempt to define the group task and to establish how they will accomplish it. As team members realize that defining the task is more difficult than expected, they move to the storming stage. Members argue about what actions the group should take. Different factions may form as conflict progresses. As the group finally reconciles competing loyalties and responsibilities, it begins to firmly establish ground rules, roles, and status. During this norming stage, members reduce emotional conflict and become more cooperative, developing a sense of cohesion and common goals. As these normative expectations take hold, the group moves to the performing stage. Members are able to prevent group problems, or to work through them

TABLE 17.2 Summary of “Classic” Group and Team Development Models

Source	Developmental Stages				
	Early Formation		Development		Disbandment
Bion (1961)	Dependency	Fight/Flight	Pairing	Work	
Caple (1978)	Orientation	Conflict	Integration	Achievement	Order
Francis & Young (1979)	Testing	Infighting	Getting Organized	Mature Closeness	
Gibb (1964)	Acceptance	Data Flow	Goals and Norms	Control	
Hill & Gruner (1973)	Orientation		Exploration	Production	
Kormanski & Mozenter (1987)	Awareness	Conflict	Cooperation	Productivity	Separation
Modlin & Faris (1956)	Structuralism	Unrest	Change	Integration	
Tuckman (1965)	Forming	Storming	Norming	Performing	
Tuckman & Jensen (1977)	Forming	Storming	Norming	Performing	Adjourning
Whittaker (1970)	(Preaffiliation)	Power and Control	Intimacy	Differentiation	
Yalom (1970)	Orientation	Conflict		Intimacy	Termination

Notes. There are some variations in the basic developmental framework across the models. Whittaker (1970) considers a preaffiliation stage. Other models incorporate a stage to represent decomposition (Kormanski & Mozenter, 1987; Tuckman & Jensen, 1977; Yalom, 1970), or later aspects of the life cycle (Caple, 1978).

Three models of work group development (not shown in the table) represent more significant departures. Gersick’s (1988) two-stage “punctuated equilibrium” model posits: (1) an immediate pattern of activity that persists to the halfway point, and (2) a transition that significantly alters the pattern of group activity as it focuses on task completion. Note that the constraints of a single project objective and limited time may limit the applicability of the punctuated equilibrium model to ad-hoc or temporary teams. Morgan, Salas, and Glickman (1993) use a nine-stage model that integrates Tuckman and Gersick, essentially repeating Tuckman’s four stages both before and after the punctuated equilibrium, and then adding a disbanding stage. Kozlowski, Gully, Nason, & Smith (1999) posit a four-phase model—team formation, task compilation, role compilation, and team compilation—that is focused on the development of team adaptive capabilities and views the process of development as compiling across levels—individual, dyadic, to team network.

In spite of these variations, most models of group development are remarkably parallel with respect to the descriptive stages. In addition, there is a stream of research that is not of direct interest here that takes a more micro focus on the developmental stages relevant to group problem-solving (e.g., Bales & Strodtbeck, 1951) and other group functions (e.g., production, well-being, and support; McGrath, 1990).

when they arise. They become closely attached to the team and satisfied with its progress as they move toward their common goal.

Implications for Work Team Development

Although classic stage models of group development provide rich descriptions of social interaction processes, they have tended to focus on the simpler types of teams—those with tasks that have undefined workflows and internally driven processes. Thus, they focus primary attention on the interpersonal ambiguity and conflict that new group members endure as they attempt to create a social hierarchy with common norms to guide interactions among members.

This focus has several implications. First, the models have not been sensitive to the organizational context. When new teams form in organizations, members typically bring socialization and cultural knowledge that reduces much—though not all—of the social uncertainty present at group formation. Second, the models have a limited conceptualization of the task, its contingencies, dynamics, and the temporal constraints these factors set on team activities (see Figure 17.2). The task is often viewed as a single incident of project planning, problem solving, or decision making that is determined by internal group dynamics; external contingencies are not acknowledged. There is no consideration of externally driven task dynamics, including variations in task complexity, difficulty, or tempo, and little recognition of multiple task episodes that cycle demands on the team. Third, the focus on unstructured task situations means that the models do not consider the development of task-relevant patterns of interaction and exchange among members that is dictated by workflow structure. Instead, group interaction is driven by interpersonal attractions and conflicts. Thus, the models tend to focus on self-insight and interpersonal processes, rather than specifying the task and team-relevant knowledge and learning that accrue during development. Fourth, the models are collectively oriented, with the group or team conceptualized as a holistic entity. This is a relevant perspective when member contributions to team outcomes represent simple aggregations. However, when composition to the higher level is represented by more complex patterns, there is a need to better disentangle the individual, dyadic, and team-level contributions. Finally, the models provide only a general description of the particular issues that arise during development, the means by which they are addressed, and the results of the process. Thus, like the socialization literature, much of the literature on team development provides relatively little insight

regarding the development of work teams. There are, however, some notable exceptions.

One of the points noted above and a central theme in this chapter is the need to consider time, its dynamics, and effects. Work teams are linked to an external context that sets the pace, tempo, and cycles of team activities (Kelly, Futoran, & McGrath, 1990), which may change over time, necessitating adaptation. This has important implications for work team development, which is not necessarily a uniform series of fixed stages. Gersick (1988, 1989), for example, observed the developmental processes of 16 project teams (8 field and 8 lab) with life cycles ranging from a week to 6 months and proposed a two-stage *punctuated equilibrium model* (PEM) of group development. Gersick's key conclusion is that group development is not dictated by a linear progression of stages. Rather, it is linked to an external deadline that paces progress. Early group interactions establish stable norms that pattern group activity through an initial period of inertia. At the halfway point, a significant transformation occurs—the punctuated equilibrium—as groups reorganize to focus on task completion. This model represents an important contribution to our understanding of group development because it acknowledges that the process is influenced by external temporal contingencies in addition to internal factors. It should also be noted that the PEM may be limited to project or problem-solving teams with a single fixed objective and limited life span, although this does capture a substantial segment of teams in organizations.

Although the PEM is often regarded as a direct challenge to stage models of development (e.g., Guzzo & Shea, 1992), some scholars view the two perspectives as distinctive, yet complementary. Chang, Bordia, and Duck (2003) contrasted Wheelan's (1994) integrative model of group development—a classic stage model—with Gersick's PEM. Examining 25 student project groups, they concluded that the models are complementary depending on (a) what content is addressed and (b) what unit of analysis is used in regard to time. Content that focused on group processes and structure and more micro timing tended to support linear development, whereas content that focused on the groups' approach to their task and more macro timing tended to support the PEM. These findings suggest that neither perspective alone is an adequate account of team development—we need broader, more integrative models.

More recently, Kozlowski and colleagues (1999) have proposed a normative model of *team compilation* that integrates team development with a performance perspective and, importantly, conceptualized team development from

a multilevel perspective. Team performance and adaptability at any given point in time are viewed as dynamic consequences of a continuous developmental process. There are three key conceptual features of the theory. First, temporal dynamics are viewed in terms of both linear and cyclical time, representing the effects of developmental processes and task episodes, respectively. Team capabilities improve developmentally prompting transition to more advanced phases of skill acquisition. Within a phase, variations in task episodes or cycles provide opportunities for learning and skill acquisition (see also Kozlowski, Gully, McHugh, et al., 1996; Kozlowski, Gully, Salas, & Cannon-Bowers, 1996). Second, developmental transitions prompt attention to different *content* that is the focus of new learning, different *processes* by which knowledge and skills are acquired, and different *outcomes* that capture current capabilities. Third, team compilation is viewed as an emergent multilevel phenomenon. Knowledge, skills, and performance outcomes compile successively upwards across focal levels from an individual self-focus to dyadic exchanges to an adaptive team network.

As illustrated in Figure 17.3, the model is formulated around four *phase* transitions, each with a distinct focal level and content, process, and outcome specifications. Unlike stages, which are discontinuous shifts, phase transitions are soft reorientations in modal activity. In phase 1, *team formation*, individuals are focused on resolving their fit in social space through a socialization process. This yields outcomes of interpersonal knowledge and team orientation, providing a foundation for shared norms, goals, and climate perceptions. In phase 2, *task compilation*, individuals focus on acquiring task knowledge via skill acquisition processes with outcomes of task mastery and self-regulation skills. In phase 3, *role compilation*, the level shifts to dyads that must negotiate role relationships, identifying key role sets and routines to guide task-driven interactions. In phase 4, *team compilation*, the level shifts to the team as it creates a flexible network of role interdependencies that will enable continuous improvement and adaptability to novel and challenging demands. Unlike most time-limited models of development, this model views team compilation as an ongoing phase rather than an end-state.

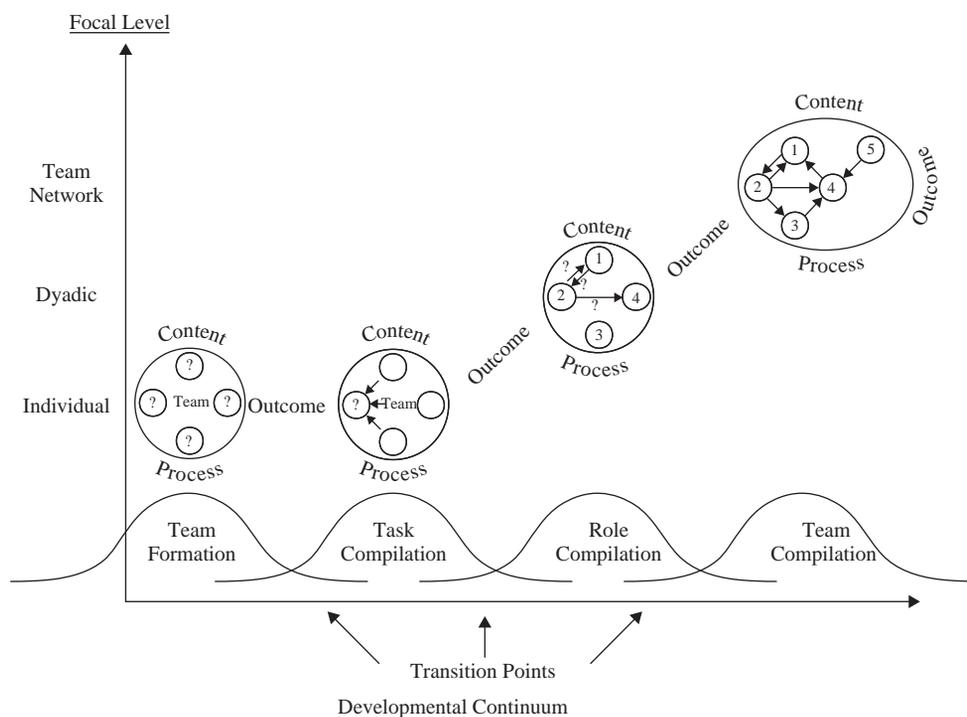

Figure 17.3 Meta theory of team development and performance compilation

There are no direct tests of this meta-theoretical model, as it is too complex to evaluate in a single study design or data collection. However, it is synthesized from a substantial and diverse literature and its core propositions are useful for generating more specific models for evaluation. For example, research by DeShon, Kozlowski, Schmidt, Wiechmann, and Milner (2001) using a team task simulation provided preliminary support for the basic proposition that developmental shifts in focal level from individual to team, versus a holistic team-level focus, contributed to team performance adaptability. Similarly, drawing on the meta theory of team compilation, research by Dierdorff, Bell, and Belohlav (2011) using a business simulation showed that different psychological collectivism facets (i.e., preference, reliance, concern, norm acceptance, and goal priority) predicted team performance during early development (preference and concern), whereas others were specific to predicting team performance in later development (goal priority). Moreover, changes in team performance over time were moderated by the quality of team member exchanges (with different collectivism facets). Although these examinations of aspects of the meta theory show promise, investigations using longer-lived teams and more realistic settings are desirable.

Research Implications and Application Issues

Socialization

At no other point are employees as malleable and open to guidance as they are during their initial encounter with the organization and their work group. This provides an obvious opportunity to have a long-term influence on the shaping of new employees that has not gone unnoticed by organizations. Indeed, the vast majority of organizations make some formal effort to socialize newcomers to inculcate norms, goals, and values via training, induction, and orientation programs (Anderson, Cunningham-Snell, & Haigh, 1996). Yet, the available evidence suggests that these formal efforts have only moderate and transitory effects, which are swamped by the more intense and proximal socialization processes that occur within work groups (Anderson & Thomas, 1996; Chao, Kozlowski, et al., 1994).

We know that team leaders and work group members play a critical role in newcomer socialization. Given this clear impact, some have suggested that it may be a useful strategy to train team leaders and group members to be more effective socialization agents (Ostroff & Kozlowski, 1992). To our knowledge, no such efforts

have been pursued and evaluated. Thus, for the most part, the effectiveness of this more local process is accidental, dependent on the mutual proaction of newcomers and their work groups. This issue has clear application potential that has not been sufficiently explored and leveraged.

While the importance of the work group as a key agent in socialization is recognized implicitly by the literature, it has largely neglected the importance of newcomer socialization *to the group*. It is in the work group's vested interest to socialize newcomers. It helps to maintain existing norms, expectations, and shared systems of meaning; it enhances social and work interactions; and it is essential to long-term group functioning. Thus, while we know how and what newcomers try to learn from work group members, we know far less about the precise role of the group in the process. What group characteristics influence the process and how? What tactics do groups use to prompt assimilation and resist accommodation? What are the effects of different group characteristics and tactics—in interaction with newcomer characteristics and tactics—on the socialization process, group functioning, and group effectiveness? These are critical research questions that for the most part remain to be explored in future research. We believe that progress on elucidating work group socialization will necessitate another shift in research perspective in the socialization literature, one that takes a contextual approach—focusing on the newcomer in the group context—one that is sensitive to multiple levels—newcomers, dyadic relationships with group members, and the group as a whole—and one that models the emergent effects of newcomer assimilation and group accommodation processes on group responses across levels and over time.

Development

Like socialization, the formative period of team development offers an unprecedented opportunity to shape the nature and functioning of new teams. Unfortunately, unlike socialization, where there is a growing empirical foundation, there is relatively little research addressing work team development. What we know about the process is largely based on extrapolations from case studies examining other types of teams (Tuckman, 1965) or on the relatively few observational studies of work team development—studies that tend to be based on very few teams. For the most part, the work team development process remains largely unexplored. This is a topic for which some basic descriptive research could be very valuable in moving theory and research forward.

In some ways, the area of team development may be paralleling and lagging its socialization counterpart. Two

decades ago, the socialization area was typified by classic descriptive theories that were primarily focused on voluntary groups. Empirical research was spotty, and not of the highest quality. Then, there was a period of theory development specifically targeted on organizational socialization that subsequently stimulated many empirical advances. Today, socialization is a vibrant area of theory development and research (Chao, 2012). The team development area is like socialization two decades ago. We are beginning to see the creation of new theories specifically focused on work team development that move beyond the classic descriptive models. Hopefully, these and other new theories will stimulate rigorous empirical research on work team development. For example, further research to validate and extend Gersick's model (1988) is needed. If the punctuated equilibrium is a universal phenomenon in project groups and other types of teams, surely interventions to accelerate the initial unproductive phase can be created to help improve the efficiency and effectiveness of the team development process. Similarly, research to validate the content, processes, and outcomes specified for the phases of team development by Kozlowski et al. (1999) would provide a foundation for creating interventions that promote team development at all stages of a team life cycle. For now, however, the process of team development, and its resulting quality, is largely taken as a matter of faith—leaders and teams are expected to muddle through and figure it out. From an applied perspective, one can't help but marvel at the magnitude of the lost opportunity to influence long-term team effectiveness.

TEAM EFFECTIVENESS, PROCESSES, AND ENHANCEMENTS

From an organizational psychology perspective, team effectiveness is the core focus of theory and research on teams and all topics addressed in this chapter bear on team effectiveness in one way or another. There are literally thousands of articles addressing it, far too many for us to capture. Our intent, therefore, is to briefly characterize key aspects of models of team effectiveness and how they have evolved, and then to focus primary attention on those topics that uniquely distinguish the organizational approach from that of its progenitors—that is, on processes relevant to work-driven team member interactions, the nature of team performance, and interventions designed to enhance team processes and team performance.

Team Effectiveness

The Nature of Team Effectiveness

Most models of team effectiveness begin where most models of team development end. Models of team effectiveness generally assume mature teams that have completed a formative developmental process. At the time of our original review in 2003, most models of team effectiveness were loosely formulated around the Input–Process–Outcome (IPO) framework posited by McGrath (1964). *Inputs* represent various resources available to the team both internally (e.g., composition of knowledge, skills, and abilities [KSAs], personalities, demographics; group structure, team design) and externally (e.g., rewards, training; organizational climate) at multiple levels (e.g., individual, group, organization). *Processes* represent mechanisms that inhibit or enable the ability of team members to combine their capabilities and behavior. Although the small-group literature has often focused on dysfunctional processes that yield process losses (Steiner, 1972), the focus of team effectiveness is on synergies that produce process gains (Hackman, 1987). *Outcomes* represent criteria to assess the effectiveness of team actions. *Team effectiveness* is generally conceived as multifaceted, with an emphasis on both internal (i.e., member satisfaction, team viability) and external (i.e., productivity, performance) criteria (Hackman, 1987). In practice, team effectiveness is broadly defined and assessed in various ways. It therefore lacks the precision of a theoretical construct; one must look to its specification for particular types of teams to determine its grounded meaning (Goodman et al., 1987; Mathieu & Gilson, 2012).

Relative to models of team development, IPO-based team effectiveness models are static in nature. This is due in large part to the assumed causal linkage inherent in the IPO heuristic, and the way that “team processes” are represented—by a box. Although theorists have acknowledged linear time (McGrath, 1964), reciprocal linkages (Hackman, 1987), and feedback loops (Tannenbaum, Beard, & Salas, 1992) to capture temporal dynamics, until recently the treatment has been latent. Thus, although the IPO framework continues to exert influence on the conceptualization of team effectiveness, it is being adapted by a push to more explicitly acknowledge the reciprocal dynamics inherent among the IPO linkages.

This push can be observed in emerging developments at the time of, and since, our prior review (Kozlowski & Bell, 2003). One aspect is the increased acknowledgment of the critical conceptual foci that undergird that

review and this one—multilevel influences, contextual constraint and creation, workflow interdependence, and temporal dynamics (Arrow et al., 2000; Kozlowski et al., 1999; Kozlowski & Klein, 2000; Marks et al., 2001). For example, building on this work and that of others, Ilgen et al. (2005) critiqued the static deficiencies of the IPO model and reformulated it as the *Input–Mediator–Output–Input* model to broaden explicitly the range of mediating processes and to accentuate the ongoing, cyclical nature of team functioning. As shown in Figure 17.4, Kozlowski and Ilgen (2006) emphasized the multilevel system context, task relevant processes, temporal dynamics, and emergent nature of team processes and effectiveness and used those conceptual foci as core themes in their review. Similarly, Mathieu, Maynard, Rapp, and Gilson (2008) advanced a conceptualization of team effectiveness that incorporated these developments: multiple, nested levels; processes and emergent states; multiple effectiveness criteria; episodic task cycles and developmental progression; and complex, reciprocal feedback linkages. Thus, although the base conceptual structure provided by the IPO framework remains viable, the conceptualization has been substantially

augmented to accommodate the complexity of teams in organizations.

Team Effectiveness Research Streams

There are some notable research streams on team effectiveness that have developed over the last couple of decades. Here we highlight three exemplars, focused on team decision making under stress, structural adaptation, and team adaptability. Sparked by major military catastrophes during the late 1980s and early 1990s caused by breakdowns in team coordination processes, research was undertaken to better understand team decision effectiveness and to develop interventions to promote it. Cannon-Bowers, Salas, and their colleagues conducted a 7-year multidisciplinary research effort—the Team Decision Making Under Stress (TADMUS) program—that was designed to improve team training and the human factors of interface design for tactical decision-making teams (TDM; Cannon-Bowers & Salas, 1998). One of the key features of the TADMUS program was its active integration of theory development, basic research, field testing, and application. The program was driven by grounded theory, which was evaluated by basic laboratory research.

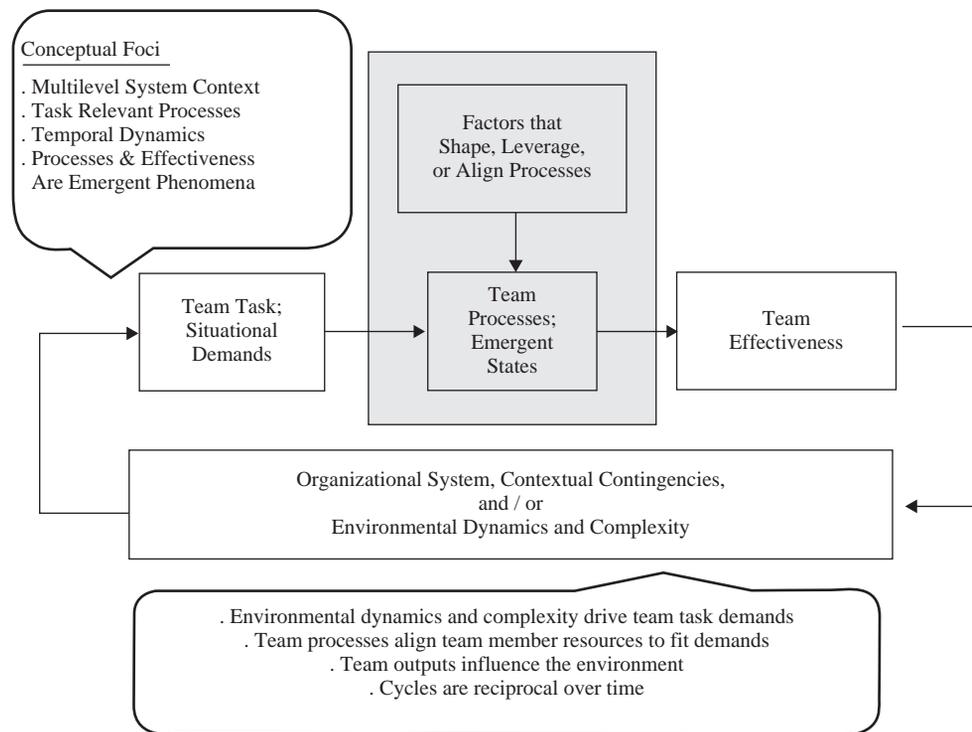

Figure 17.4 Kozlowski and Ilgen (2006) team effectiveness heuristic

Adapted from Kozlowski, S. W. J., & Ilgen, D. R. (2006). Enhancing the effectiveness of work groups and teams (Monograph). *Psychological Science in the Public Interest*, 7, 77–124. Copyright © Sage. Used with permission.

Promising findings were subject to field testing to ensure generalization to the operational environment. Finally, proven techniques were implemented and institutionalized. TADMUS represents an excellent example of the way that theory and basic research can transition to effective organizational application.

Another good example of systematic research on team effectiveness is the line of inquiry conducted by Ilgen, Hollenbeck, and their colleagues. Their early work focused on a theory of decision making for hierarchical teams with distributed expertise, in which team members possess distinctive roles and have access to different decision-relevant information (Ilgen et al., 1995). Hollenbeck et al. (1995) introduced the theory and tested it in two research contexts showing that team leaders are generally sensitive to the quality and accuracy of the advice they receive from team members and, over time, adjust accordingly. Subsequent research established boundary conditions and investigated more model specifics (e.g., Hollenbeck, Colquitt, Ilgen, LePine, & Hedlund, 1998). The next phase of their research focused on asymmetries in structural adaptation (e.g., Hollenbeck et al., 2002; Moon et al., 2004). A long-standing premise of organizational design is based on the notion that organizations adapt their structure to fit environmental and task contingencies. As environments shift, so goes the theory, organizations adapt their structure to be aligned with the changes; appropriate alignments are assumed to be symmetrical. Replicating well-established findings at the organizational level, teams in predictable environments were more effective under a functional structure (i.e., distinct specializations), whereas a divisional structure (i.e., generalist capabilities) was superior in unpredictable task environments. However, when the task environment shifted, they found that there were asymmetries. Teams were able to adapt from a functional to a divisional structure, but moving from divisional to a functional structure was problematic. Essentially, functional structures necessitated coordination and cooperation, whereas divisional structures did not. Recent theoretical work represents an effort to develop an integrated conceptualization of task interdependence and team structure (Hollenbeck & Spitzmuller, 2012).

Finally, one of the important developments stemming from theoretical attention to the dynamics of team task processes, developmental progress, and effectiveness has been interest in team performance adaptation. For example, Kozlowski and colleagues conceptualized team tasks as embodying ongoing task cycles that varied the load placed on members. By integrating the task cycles

with a regulatory model, they developed a normative theory to prescribe how leaders could develop adaptive teams (Kozlowski, Gully, McHugh, et al., 1996; Kozlowski, Gully, Salas, et al., 1996) and a normative theory to explain how adaptive capabilities compiled over time and focal levels—individual, dyad, and team network—to enable adaptive teams (Kozlowski et al., 1999). Subsequent theorizing developed an integrative multidisciplinary, multilevel, and multiphase model of team adaptation (Burke, Stagl, Salas, Pierce, & Kendall, 2006). An excellent exemplar of empirical work in this area is provided by LePine (2005), who studied how team members adapted to a change in their environment that unfolded over time. In the next sections, we focus on team processes that need to be appropriately aligned with dynamic team task demands for teams to be effective, and on those enhancements that can shape alignment. This naturally raises the question, What team process mechanisms enable team effectiveness?

Team Processes

Like the effectiveness area, there is an extensive literature on team processes. At the point of our prior review, there was little convergence on a core set of processes for work teams and we organized our review around cognitive, affective/motivational, and behavioral processes that were viewed as supportive of effective team functioning. Kozlowski and Ilgen (2006) followed that organization and, further, focused their review on identifying those team processes linked to team effectiveness that had amassed solid meta-analytic support or a stream of promising research findings (see Figure 17.4). They then shifted attention to identify those interventions with demonstrated support or solid findings that could shape core team processes. This had the effect of sifting through a large volume of hypothesized team processes (or what Marks et al. (2001) describe as “emergent states”) to focus on those with the most relevance and promise for influence and application. We build on those developments in this updated review.

Cognitive Constructs and Mechanisms

In this section, we examine four primary cognitive mechanisms that are represented in the literature: team learning, team mental models, transactive memory, and macrocognition. *Team learning* is a broad concept that has been examined from a number of different research perspectives (Edmondson, Dillon, & Roloff, 2007). In a recent review of this literature, Bell, Kozlowski, and Blawath

(2012) argue that team learning is a multilevel (individual *and* team, not individual *or* team), dynamic (iterative and progressive; a *process* not an *outcome*), and emergent (outcomes of team learning can manifest in different ways over time) phenomenon. They present a conceptual framework designed to provide a theoretical integration of team learning and to more clearly distinguish between the processes that underlie team learning, including information processing, regulation, and macrocognition, and the knowledge (e.g., team mental models, transactive memory) and other emergent states (e.g., team efficacy, cohesion) that result from these processes and ultimately shape team effectiveness.

Research conducted over the past decade has begun to elucidate the effects of team learning on team effectiveness as well as the factors that support and facilitate the process of team learning. Van der Vegt and Bunderson (2005), for instance, showed that team learning was positively associated with the performance of multidisciplinary teams in the oil and gas industry and that it mediated the effect of expertise diversity and collective identification on team performance. Similarly, Ellis et al. (2003) found that team learning behaviors positively predicted the performance of teams performing a command and control simulation. Wong (2004) found that local team learning (i.e., learning with individuals in the immediate team) had a positive effect on group efficiency, whereas distal team learning (i.e., learning with individuals external to the group) facilitated group innovativeness. Furthermore, she found evidence of potential trade-offs between local and distal team learning—local learning had a positive effect on group efficiency when distal learning was low or moderate, but it was unrelated to efficiency when distal learning was high.

Edmondson's (1999) model of team learning suggests that psychological safety—a shared belief that the team is safe for interpersonal risk taking—contributes to team learning behaviors, such as seeking feedback, sharing information, experimenting, asking for help, and talking about errors. These behaviors are then presumed to facilitate performance by allowing the team to shift directions as situations change and discover unexpected implications of team actions. Subsequent research has shown that leaders play a key role in shaping the psychological safety climate within their teams (Edmondson, Bohmer, & Pisano, 2001; Nembhard & Edmondson, 2006). A recent study by Porter, Webb, and Gogus (2010) found that team learning orientation influenced the adaptive performance of teams performing a command and control simulation, but the nature of this relationship depended on both team

performance orientation and the availability of resources. De Dreu (2007) showed that information sharing, team learning, and team effectiveness were higher when team members perceived higher levels of cooperative outcome interdependence. However, the positive effects of cooperative outcome interdependence were only found when teams engaged in deliberate and systematic information processing.

Although this work is still in its formative stage, some research and practical recommendations may be noted. From a research perspective, the empirical work is weak. First, and most critically, learning or knowledge is rarely assessed directly. Instead, team learning is assumed from changes in team performance and/or behavior. Thus, there is a clear need for research to directly measure changes in both individual and team knowledge and to separate the process of team learning from not only the knowledge-based outcomes and emergent states that emerge from this process but also team performance (Bell et al., 2012). Until these issues are addressed, the standing of team learning as a meaningful and useful construct remains murky. A second and related limitation is that many of the variables examined as having an impact on team learning, such as turnover, may have impacts on team performance apart from affecting team learning. In other words, while turnover may impact the “collective” knowledge of the team, it also may influence communication patterns, induce socialization efforts, affect collective efficacy, and so forth, which may ultimately impact team performance. Thus, it is important for researchers to demonstrate that variables, such as turnover and task complexity, have an impact directly on team learning. Finally, more research is needed to understand the process by which team learning occurs. What are the conditions that facilitate team learning? How is the process different from individual learning? How does team learning emerge from individual learning? And, how can team learning be facilitated and shaped? There are levels of analysis issues that need to be explicitly addressed to better understand whether the process of learning is similar or different at the individual and team levels (Kozlowski & Klein, 2000; Wilson, Goodman, & Cronin, 2007).

Team mental models are team members' shared, organized understanding and mental representation of knowledge about key elements of the team's task environment (Klimoski & Mohammed, 1994). Four content domains underlying team mental models have been proposed (Cannon-Bowers, Salas, & Converse, 1993):

1. Equipment model—knowledge of equipment and tools used by the team.

2. Task model—understanding about the work that the team is to accomplish, including its goals or performance requirements and the problems facing the team.
3. Member model—awareness of team member characteristics, including representations of what individual members know and believe, their skills, preferences, and habits.
4. Teamwork model—what is known or believed by team members with regard to what are appropriate or effective processes.

Related to team mental models, but at a much higher level of generality, are conceptualizations of *team climate*. Team climate represents group-level shared perceptions of important contextual factors that affect group functioning, via mediating climate perceptions that affect group outcomes. For example, Hofmann and Stetzner (1996) have demonstrated that team safety climate affects team safety behaviors and outcomes. Similarly, Bunderson and Sutcliffe (2003) showed that members' shared perceptions of the team's learning orientation influence team performance. Variations in the extent to which climate is shared at the team level have been shown to affect its linkage with team outcomes (González-Romá, Peiró, & Tordera, 2002).

The general thesis of the shared mental model literature and its variants is that team effectiveness will improve if members have an appropriate shared understanding of the task, team, equipment, and situation (e.g., Cannon-Bowers et al., 1993). At the time of our last review, empirical work lagged behind conceptual development (Mohammed & Dumville, 2001). However, there has been a proliferation of empirical studies on shared team mental models over the past decade and this body of work generally supports the notion that appropriate team mental models have positive effects on team processes and effectiveness (Mohammed, Ferzandi, & Hamilton, 2010). For example, Smith-Jentsch, Mathieu, and Kraiger (2005) examined the effects of two types of mental models—team interaction and task—on team effectiveness in an air traffic control environment. They found that tower safety and efficiency were highest when air traffic controllers held consistent team interaction and task shared mental models. A recent meta-analysis by DeChurch and Mesmer-Magnus (2010) revealed strong positive relationships between team cognition and team behavioral processes, motivational states, and performance. However, they also provide evidence that the conceptualization and operationalization of cognition moderate these relationships. For instance, the effects of cognition on behavioral processes and performance

were stronger for compilational cognition (e.g., transactive memory) than compositional cognition (e.g., shared mental models). In addition, they found that compositional cognition was more strongly predictive of team performance under conditions of moderate, rather than high, team interdependence and in project and decision-making teams than in action teams. Overall, these meta-analytic findings support the positive relationship between mental models and team effectiveness, but also suggest that the magnitude of this relationship depends on a number of factors, including the form and content of the mental models as well as the nature of the team, the tasks it performs, and the outcomes that are measured.

These research findings suggest that the development of team mental models is a promising leverage point for interventions to improve team effectiveness. Several methods for fostering the development of team mental models have been proposed, including team planning (Stout, Cannon-Bowers, Salas, & Milanovich, 1999), computer-based instruction (Smith-Jentsch, Milanovich, Reynolds, & Hall, 1999), and team self-correction training (Blickensderfer, Cannon-Bowers, & Salas, 1997). For example, team self-correction training involves the following elements: (a) event review, (b) error identification, (c) feedback exchange, and (d) planning for the future. Team self-correction can be enhanced through training in skills such as providing feedback, situational awareness, and assertiveness. Similarly, Kozlowski and colleagues (Kozlowski, Gully, McHugh, et al., 1996; Kozlowski, Gully, Salas, et al., 1996) posit that leaders can play a central role in developing team coherence by leading the team through an iterative four-step *learning cycle* that makes use of (a) goal setting, (b) performance monitoring, (c) error diagnosis, and (d) process feedback. Providing support for these perspectives, Marks, Zaccaro, and Mathieu (2000) enhanced team mental models with leader prebriefs regarding effective strategies to use. Smith-Jentsch, Zeisig, Acton, and McPherson (1998) also used structured leader pre- and debriefs to enhance team mental models and performance.

Transactive memory is a group-level shared system for encoding, storing, and retrieving information—a set of individual memory systems that combines knowledge possessed by particular members with shared awareness of who knows what (Wegner, 1986; Wegner, Giuliano, & Hertel, 1985). It was introduced to explain how intimate relationships (i.e., dating couples) foster the development of shared memory. The development of transactive memory involves communicating and updating information each partner has about the areas of the other's knowledge.

In essence, each partner cultivates the other as an external memory aid, and in so doing becomes part of a larger system. The application of the concept to work teams involves a similar logic. Each team member keeps current on who knows what, channels incoming information to the appropriate person, and has a strategy for accessing the information (Mohammed & Dumville, 2001). In addition to knowing who is the expert in different knowledge areas, transactive memory also involves storing new information with individuals who have matching expertise and accessing relevant material from others in the system (Wegner, 1986, 1995).

Transactive memory is presumed to offer teams the advantage of cognitive efficiency. Through the encoding and information allocation processes, individual memories become progressively more specialized and are fashioned into a differentiated collective memory that is useful to the group. The knowledge specialization that individuals develop within a transactive memory system reduces cognitive load, provides access to an expanded pool of expertise, and decreases redundancy of effort (Hollingshead, 1998b). On the downside, however, the complexity of transactive memory can create confusion, especially when expertise is in dispute and important information falls through the cracks (Pearsall, Ellis, & Bell, 2008; Wegner, 1986). There is also the potential problem of time lags to acquire needed information. When performance is time critical, such lags are likely to adversely affect team effectiveness.

Because the concept was introduced to explain the behavior of intimate couples, much of the early research in this area examined dyads (e.g., Hollingshead, 1998a, 1998b). However, more recent work has addressed transactive memory in work groups. Austin (2003), for instance, examined the effects of transactive memory on the performance of groups in an apparel and sporting goods company. He found that the accuracy and specialization dimensions of transactive memory were positively related to several different measures of team performance. As noted above, the meta-analysis by DeChurch and Mesmer-Magnus (2010) showed that compilational cognition, which is consistent with the transactive memory tradition, is a stronger predictor of behavioral processes and team performance than compositional cognition. The authors argue that compilational cognition offers greater predictive power because the patterned knowledge that emerges is nonisomorphic to the individual-level cognitive content. Unlike compositional cognition, the relationship between compilational cognition and team

performance was similar across levels of team interdependence. In addition, compilational cognition exhibited a stronger relationship with team performance in action and project teams than in decision-making teams.

Given its positive relationship with team performance, a number of studies have explored factors that influence the development of transactive memory systems. Pearsall, Ellis, and Bell (2010), for example, showed that communication about roles and responsibilities in the early stages of a team's development cycle is important to the development of transactive memory. A number of studies have also shown that disruptions in team membership (i.e., turnover) impede the development and functioning of transactive memory systems (Akgün Byrne, Keskin, Lynn, & Imamoglu, 2005; Lewis, Belliveau, Herndon, & Keller, 2007). Other research provides evidence that transactive memory development can be influenced by task and outcome interdependence (Lewis, 2003; Zhang, Hempel, Han, & Tjosvold, 2007), team member personality (Pearsall & Ellis, 2006), and acute stress (Ellis, 2006).

Although research on transactive memory has gained momentum in recent years, this area is still in its infancy (Kozlowski & Ilgen, 2006). From a research perspective, the measurement of transactive memory merits additional consideration. Although transactive memory is a compilational construct (Kozlowski & Klein, 2000), the instrument used to assess it most often (i.e., Lewis, 2003) does not directly assess the distributed memory structure. Instead, team member perceptions of knowledge distribution are assessed and then mean ratings are used as indicators of transactive memory facets, with aggregation justified based on an examination of restricted within-group variance (i.e., justification for aggregating a composition construct). This inconsistency between the conceptualization and operationalization of transactive memory raises questions as to what is actually being captured by the measure (Kozlowski & Chao, 2012b). From a practical perspective, research suggests that the nature of communication media in teams may be important for fostering and maintaining transactive memory. Hollingshead (1998b), for example, found that couples working via a computer conferencing system performed more poorly on a knowledge-pooling task than couples who worked face-to-face. Those results and a follow-up suggest that both nonverbal and paralinguistic communication play an important role in the retrieval of knowledge in transactive memory systems, which has important implications for the development of transactive memory systems in virtual teams where computer-mediated communication

is the norm. Finally, research by Moreland and colleagues (Liang, Moreland, & Argote, 1995; Moreland & Myaskovsky, 2000) suggests that training intact teams may be useful for developing transactive memory systems.

Macro cognition is a concept used to describe cognition in naturalistic decision-making settings (Cacciabue & Hollnagel, 1995). Extending this concept to team learning in collaborative contexts, Fiore and colleagues (Fiore, Rosen, Smith-Jentsch, Salas, Letsky, & Warner, 2010) developed a theoretical framework for macrocognitive knowledge building involved in team decision making. They conceptualize macrocognition as a process of individual team members building *internalized knowledge* that is then transformed to team knowledge through a process of information exchange and sharing that yields *externalized knowledge*. Externalized knowledge, shared among team members, can then be applied to generate problem solutions, courses of action, and decision options that team members vet, select, and execute.

Kozlowski and Chao (2012a), and their research team (Kozlowski, Chao, Grand, Keeney, Braun, & Kuljanin, 2011), have developed a *team knowledge typology* (TKT) to capture team knowledge that emerges from the core processes of the Fiore et al. (2010) model of macrocognition. The TKT is a conceptually based measurement model that is multilevel, dynamic, and emergent and, although not an explicit integration, it incorporates features of collective knowledge (i.e., team knowledge as a collective pool), team mental models (i.e., team knowledge as a shared property), and transactive memory (i.e., team knowledge as a configuration of distributed knowledge). A basic assumption of the approach is that team knowledge emergence as a multilevel phenomenon is not just composition based (e.g., team mental models) or just compilation based (e.g., transactive memory), but rather it ranges across a spectrum of emergence types (Kozlowski & Klein, 2000).

The TKT represents macrocognitive knowledge as (a) *pools* of individual and collective (overlapping or shared) team knowledge; (b) *configurations* that capture patterns of distinct individual, dyadic, and collective knowledge; and (c) *variance* in the rates of knowledge building and its emergence at the team level, both within and across teams, over time. The knowledge types, definitions, examples, and descriptions are illustrated in Figure 17.5. Preliminary validation has been conducted (Kozlowski et al., 2011) and research to examine the diagnostic potential of the metrics to improve macrocognition and team decision effectiveness is in progress. Because the TKT is a conceptually based measurement model,

a specific task and knowledge domain is necessary to ground operationalization of metrics. Thus, the TKT is designed to be a generalizable measurement model that can be applied across a range of different collaborative team tasks to assess the emergence of team knowledge.

Affective and Motivational Constructs and Mechanisms

There are four primary team process constructs or mechanisms that can be classified as affective, affectively related, or motivational in nature: (a) cohesion, (b) team affect or mood, (c) collective efficacy, and (d) conflict and divisiveness. We address each of these processes in turn.

Team researchers have offered multiple definitions of *cohesion*. Festinger (1950) defined cohesiveness as “the resultant of all the forces acting on the members to remain in the group” (p. 274). Goodman et al. (1987) defined cohesion as the commitment of members to the group’s task. Evans and Jarvis (1980) concluded that “member attraction to the group” (p. 360) is the most common definition of cohesion. Mixed results for the effects of cohesion on performance, however, have led researchers to suggest that it may be multidimensional. Gross and Martin (1952) described cohesion in terms of two underlying dimensions, task cohesion and interpersonal cohesion. Task cohesion is defined as a group’s shared commitment or attraction to the group task or goal, and is thought to increase commitment to the task and to increase individual effort by group members on the task. Interpersonal cohesion is defined as the group members’ attraction to or liking of the group (Evans & Jarvis, 1980). Interpersonal cohesion allows groups to have less inhibited communication and to effectively coordinate their efforts.

Research findings tend to support the multidimensional view. For example, a meta-analysis by Mullen and Copper (1994) distinguished three types of cohesion: (a) interpersonal cohesion, (b) task cohesion, and (c) group pride. They concluded that task cohesion is the critical element of group cohesion when the cohesion-performance relationship is examined, and that interpersonal cohesion might do little more than cause members to exert only as much effort as required to remain in the group. However, a more contemporary meta-analysis by Beal, Cohen, Burk, and McLendon (2003) found that all three dimensions of cohesion significantly related to group performance and the magnitude of the effects did not significantly differ across the three dimensions. Zaccaro and Lowe (1988) found that only task cohesion was important for an additive task; interpersonal cohesion had no impact. On a disjunctive task, however, Zaccaro and McCoy (1988) found that the best group performance occurred when groups

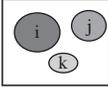

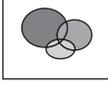

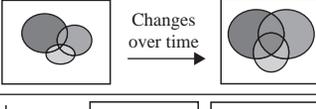

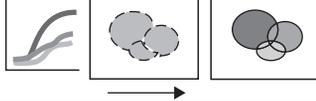

Knowledge Metrics	Brief Description	Example
Individual Knowledge	The proportion of the total pool of possible knowledge possessed by each team member separately	 The amount of knowledge individuals i, j, and k each possess within the problem space
Knowledge Pool	The proportion of the total pool of possible knowledge possessed by each team collectively	 The proportion of the total knowledge among individual team members not accounting for overlap
Knowledge Configuration	The proportion of the total pool shared in common by team members and the pattern of unique knowledge held across individuals	 Understanding what is common and what is unique knowledge among team members
Knowledge Acquisition	The rate of knowledge compiled by each team member over time	 How fast an individual learns (expands a circle in above Venn diagrams)
Knowledge Variability	Within-team variance in the rates of Knowledge Acquisition	 Different rates of knowledge acquisition can affect a team's learning
Knowledge Emergence (within team)	The rates of growth of Knowledge Pool and Knowledge Configuration	
Knowledge Emergence (between)	Comparing growth rates for Knowledge Variability, Knowledge Pool, and Knowledge Configuration across teams

had high levels of both task cohesion and interpersonal cohesion.

Although it has been observed that a cohesive group may engage its energies in high performance *or* its restriction (Seashore, 1954), most empirical research has supported a positive relationship between cohesion and group performance across a wide variety of team types (Evans & Dion, 1991; Greene, 1989; Hambrick, 1995; Katzenbach & Smith, 1993; Mullen & Copper, 1994; Smith et al., 1994). However, several important issues remain to be firmly resolved with respect to the effects of cohesion on team effectiveness. First, the relative impacts of the different dimensions of cohesion may depend on the effectiveness outcome being examined. For example, Beal et al. (2003) found cohesion was more strongly related to performance behaviors than performance outcomes and was more strongly related to measures of performance efficiency than measures of performance effectiveness. However, these are relatively broad categories of outcomes, so future research is needed to provide a more fine-tuned picture of the effects of cohesion on different aspects of team

effectiveness. Second, task type may operate as a moderator of cohesion effects. Gully, Devine, and Whitney (1995) suggested that cohesive groups perform well on interdependent tasks because they can coordinate better, whereas coordination is unimportant for more independent tasks. Gully et al. supported this hypothesis in their meta-analysis. Beal et al. (2003) provided further support for this assertion by showing that the cohesion–performance relationship became stronger as team workflow increased. Research is needed to further understand the effects of cohesion across different workflow arrangements, as some researchers have suggested that cohesion can be detrimental for additive tasks because it partially focuses group effort onto social development rather than concentrating just on the task (Lott & Lott, 1965).

Two practical recommendations can be offered for enhancing team cohesion. First, it may be important to have the right mix of individuals to enhance team cohesion. Barrick et al. (1998) found that teams high in extraversion and emotional stability had higher levels of social cohesion. Second, clear norms and goals

may help teams to develop both task and interpersonal cohesion, although it is difficult to know precisely the direction of this relationship. Thus, using selection to manage group composition and team development to inculcate norms and goals may be useful ways to establish cohesive groups.

Team affect or mood captures the idea of group affective tone. Barsade and Gibson (1998) argue that two approaches—top-down and bottom-up—can be used to understand group emotion. The top-down approach views the group as a whole and leads researchers to examine how the feeling and behaviors of individuals arise from group dynamics. It is characterized by four streams of research that treat group emotion as:

1. Powerful forces that dramatically shape individual emotional response (e.g., psychological effects of crowds).
2. Social norms that prescribe emotional feelings and expression (e.g., sets of socially shared norms about how individuals should feel and how they should express those feelings in particular situations).
3. The interpersonal glue that keeps groups together (e.g., group cohesion).
4. A window to viewing a group's maturity and development (e.g., group emotions have been used to understand the temporal development of groups).

The bottom-up approach examines the ways in which individual-level emotions combine at the team level to influence outcomes, and is represented by three research foci: (a) mean level affect, (b) affective homogeneity/heterogeneity, and (c) the effects of minimum–maximum team member affect on the group.

Shaw (1976) suggested that there is consistent evidence that group effectiveness, cohesiveness, morale, group motivation, and communication efficiency are positively related to the composition of such individual-level attributes as adjustment, emotional control, and emotional stability, and negatively related to such attributes as depressive tendencies, neuroticism, paranoid tendencies, and pathology. Some researchers have suggested that affective homogeneity is beneficial because research has shown that similarity between individuals creates attraction (Schneider, 1987). Similar to the effects of group composition, it has been argued that teams with members who are more similar affectively will be more comfortable with each others' interpersonal interactions, thereby generating more cooperation, trust, social integration, and cohesion. This in turn should positively influence

group outcomes. For example, Barsade, Ward, Turner, and Sonnenfeld (2000) examined the dispositional positive affective similarity among members of senior management teams and found that affective similarity has a positive effect on group outcomes. However, some group composition research has shown that affective heterogeneity can be beneficial for some outcomes such as creativity (Jackson, 1992b). Barsade and Gibson (1998) suggest that it may be good when the affective qualities of individuals complement one another (e.g., pessimist and optimist, low energy and high energy, etc.). Finally, it may be possible to take the idea of minority influence and examine it from an affective perspective. Barsade (2002) suggests that a single person can have a strong influence on group affect. A person who has strong dispositional negative affect, or vice versa, may infect the team with his or her negativity and the team's mood may become much more negative than would be expected from its mean-level dispositional affect.

Although the ideas regarding the effects of team affect on team effectiveness are provocative, several important issues need to be resolved. First, more empirical support is needed. Most of Barsade's ideas are drawn from research on group composition and other topics. Barsade draws parallels suggesting that similar effects may occur when the compositional variable of interest is affect. However, aside from a few empirical studies, most of these issues remain unexamined. Research is clearly needed. Second, research is needed on the factors that influence the development of team affect. Bartel and Saavedra (2000) showed that mood convergence was positively associated with teams' membership stability, task and social interdependence, and mood-regulation norms. Sy, Côté, and Saavedra (2005) found that leaders' mood had effects on both individual mood and group affective tone. Finally, Barsade and Gibson (1998) make clear reference to top-down and bottom-up levels of analysis issues. It is important for research to address these issues with precision to better understand the impact of group-level affect on individual-level variables and vice versa (Kozlowski & Klein, 2000).

The potential practical implications of this work are tempered by the need for more basic research. For example, while there is some support for a relationship between dispositional affect and job skills (see Staw, Sutton, & Pelled, 1994, for a review), the research is not yet specific enough to be able to determine how this would transfer across different group contexts. Such research is necessary to determine the most effective ways of influencing group outcomes through affect. Is

it best to control group affect by establishing norms, or will it be more effective to select team members based on affective individual differences? Similarly, managers may need to influence the impact of maximum and minimum group members because these members—through contagion—can have a strong influence on the affect of the group. Or there may be a need to manage affective heterogeneity or homogeneity. Selection as a means to manage group composition may be a useful tool in this regard. However, far more research will have to be conducted before there is a sufficient foundation for specific practical recommendations.

Bandura's (1997) concept of *collective efficacy* is defined as a group's shared belief in its own collective ability to organize and execute courses of action required to produce given levels of attainment. Zaccaro, Blair, Peterson, and Zazanis (1995, p. 309) defined collective efficacy as "a sense of collective competence shared among members when allocating, coordinating, and integrating their resources as a successful, concerted response to specific situational demands." Shea and Guzzo (1987, p. 335) defined a similar construct, called *group potency*, as "the collective belief of a group that it can be effective." Although many scholars view these two constructs as similar, Guzzo, Yost, Campbell, and Shea (1993) asserted that collective efficacy is task specific and group potency is a more general shared belief about group effectiveness across multiple tasks. It is generally presumed that a well-developed structure and interactive or coordinative task processes are necessary or at least a sufficient condition for shared efficacy beliefs to develop (Paskevich, Brawley, Dorsch, & Widmeyer, 1999). In other words, there needs to be a common foundation to foster shared judgments of future effectiveness. Similar to individual-level efficacy, collective efficacy is hypothesized to influence what a group chooses to do, how much effort it will exert in accomplishing its goal, and its persistence in the face of difficulty or failure (Bandura, 1986).

Some of the initial research examining the effects of collective efficacy focused on physical tasks and the performance of sports teams. For example, Hodges and Carron (1992) found that triads high in collective efficacy improved their performance on a muscular endurance task following a failure experience, whereas triads low in collective efficacy experienced a performance decrement. In the field, Feltz and Lirgg (1998) found that ice hockey teams with higher levels of collective efficacy performed better. Similar results have been reported for work teams. Virtually all the studies that have examined this issue have found a positive relationship between collective

efficacy and work team effectiveness (e.g., Campion et al., 1993; DeShon, Kozlowski, Schmidt, Milner, & Wiechmann, 2004; Edmondson, 1999; Hyatt & Ruddy, 1997). In addition, a meta-analysis by Gully, Incalcaterra, Joshi, and Beaubien (2002) examining 114 effect sizes from 67 empirical studies concluded that team efficacy is a strong predictor of team performance ($\rho = 0.35$).

There are three important issues that need to be addressed by continuing research on collective efficacy: (a) levels of analysis concerns in measurement; (b) the role of team efficacy within a broader framework of team learning, motivation, and performance processes; and (c) examination of potential contextual moderators. First, Gist (1987) suggested three methods of assessing collective efficacy: (a) aggregating individual perceptions of *self-efficacy*; (b) averaging individuals' perceptions of *collective efficacy*; or (c) using consensual group responses to a single questionnaire. However, levels of analysis theorists recognize these alternatives as distinctly different conceptualizations of the higher level construct relative to its individual-level origins (e.g., Chan, 1998). Indeed, Gully et al. (2002) found that effects on team performance were stronger when team efficacy was measured at the team level ($\rho = 0.39$) than the individual level ($\rho = 0.20$) of analysis. Thus, collective efficacy should be appropriately measured and composed to the team level using a reference-shift aggregation model rather than an additive or direct consensus model (Kozlowski & Ilgen, 2006). Second, although the relationship between team efficacy and team performance is well established, what is less clear is the role of team efficacy in a broader conception of team learning, motivation, and performance. DeShon et al. (2004) provided support for a homologous multilevel model of individual and team regulation, which suggests that team efficacy operates similar to self-efficacy in action initiation and control at the team level. Recent research by Chen, Kanfer, DeShon, Mathieu, and Kozlowski (2009) tested a dynamic, cross-level model of motivation in teams and found that the relationship between prior team performance and self-efficacy was mediated by team efficacy and that the effect of team efficacy on subsequent individual goal striving was mediated by self-efficacy and team action processes. Bell et al. (2012) also highlight team efficacy as an emergent state that is reciprocally entwined with team learning. Thus, evidence is mounting that team efficacy is one part of a broader process of team motivation and learning. Third, it is likely that contextual factors such as the team task and culture, among others, may affect the linkage between collective efficacy and team effectiveness. Gibson (1999)

found that when task uncertainty was high, work was independent, and collectivism was low, group efficacy was not related to group effectiveness. However, when task uncertainty was low, work was interdependent, and collectivism was high, the relationship between group efficacy and group effectiveness was positive. Similarly, the meta-analysis by Gully et al. (2002) revealed that the relationship between team efficacy and performance was stronger when interdependence was high ($\rho = 0.45$) rather than low ($\rho = 0.36$).

Based on the supportive research findings, it is reasonable to assert that high collective efficacy is generally a desirable team characteristic. From a practical perspective, the relevant question is, How can collective efficacy be fostered? Unfortunately, most research has examined the collective efficacy–performance relationship. There has been much less attention focused on the antecedents of collective efficacy, making it difficult to provide firm recommendations on how managers and organizations can build efficacy at the team level. However, one might assume that many of the factors shown to influence individual-level self-efficacy may be relevant, at least as a point of departure. Thus, future research should consider team-level goal orientation (DeShon et al., 2004), regulatory focus (DeShon et al., 2001), attributional processes, and success/failure experiences (Bell & Kozlowski, 2011), especially early in a team's life cycle.

Most of the process constructs and mechanisms discussed thus far are oriented toward forces that push team members together. Shared mental models, team learning, cohesion, and collective efficacy are forces for convergence. And, clearly, the image of a team as a “well-oiled machine” characterizes our interest in those processes that yield synergy and the enhancement of team effectiveness. Yet, it is also the case that teams are not always characterized by convergence. Indeed, *divergence*, *divisiveness*, and *conflict* are common phenomena in teams and organizations (Brown & Kozlowski, 1999). For example, Lau and Murnighan (1998) describe how demographic differences can split a group along “faultlines” into competing and divisive entities. Brown and Kozlowski (1999) present a Dispersion Theory that focuses on latent constructs (e.g., perceptions, values, beliefs). In their model, convergent and divergent processes can operate simultaneously within and across groups, affecting the nature of emergent collective constructs (see also Kozlowski & Klein, 2000). Sheremata (2000) argues that groups and organizations are characterized by both centrifugal forces—which push the entity apart—and centripetal forces—which pull it back together.

Conflict is a manifestation of the processes underlying faultlines, divergence, and centrifugal forces. Work teams provide an interpersonal context in which conflict is likely; it must then be managed because it is often detrimental to team performance (Jehn, 1995). Marks et al. (2001) identified two conflict management strategies: (a) preemptive conflict management involves establishing conditions to prevent, control, or guide team conflict before it occurs; whereas (b) reactive conflict management involves working through task, process, and interpersonal disagreements among team members. Most research has focused on reactive conflict management strategies, such as identification of the parameters of conflict between team members, problem solving, compromising, openness and flexibility, and willingness to accept differences of opinion. Although more limited, there has been some work on preemptive conflict management such as establishing norms for cooperative rather than competitive approaches to conflict resolution (Tjosvold, 1985), using team contracts or charters to specify a priori how team members agree to handle difficult situations (Smolek, Hoffman, & Moran, 1999), and developing team rules and norms about the nature and timing of conflict (Marks et al., 2001).

Recent research has shed light on several important aspects of intra-team conflict and provides promise for developing better conflict management in teams. Some research suggests that conflict may be beneficial for teams; it depends on the types of conflict and task. For example, Jehn (1995) found that for groups performing routine tasks, both task conflict (disagreement about task content) and relationship conflict (interpersonal incompatibilities) were detrimental. However, for groups performing nonroutine tasks, only relationship conflict was detrimental. In fact, at times, task conflict was beneficial for groups performing nonroutine tasks. Similarly, Amason (1996) found that higher levels of cognitive conflict (task based) and lower levels of affective conflict (relationship based) led to increased effectiveness in top management teams. Furthermore, research by Simons and Peterson (2000) found that top management teams low in interpersonal trust tended to attribute conflict to relationship-based issues, whereas top management teams high in interpersonal trust tended to attribute conflict to task-based disagreements. However, De Dreu and Weingart (2003) present meta-analytic findings that indicate that both task and relationship conflict are negatively associated with team member satisfaction and team performance. In contrast to the findings noted above, they also found that the negative relationship between conflict and team performance was stronger for teams performing

complex, uncertain tasks, which supports the perspective that conflict interferes with information processing capacity. When examined in its totality, the literature suggests that conflict is generally detrimental to team effectiveness, but may, under very specific conditions, have positive consequences (De Dreu & Weingart, 2003). Thus, future research is needed to identify those conditions.

Behavioral Constructs and Mechanisms

This is one area that has seen conceptual and empirical progress since our prior review in 2003. At that time, we identified three broad observable process mechanisms that influence team effectiveness: (a) coordination, (b) cooperation, and (c) communication. They can be distinguished in that coordination involves a temporal component that is not an essential part of cooperation or collaboration, and communication is a means for enabling coordination or cooperation. Over the past decade, a behavioral process taxonomy proposed by Marks et al. (2001) has gained conceptual prominence, solid empirical support, and application. We highlight both the broader conceptualization and this newer, better differentiated conceptualization that is appropriate for action teams (Sundstrom et al., 1990).

Coordination can be defined as activities required for managing the interdependencies of the team workflow. The notions of (a) integrating disparate actions together in concert with (b) temporal pacing or entrainment are central to the conceptualization of coordination (Argote & McGrath, 1993). Coordination is vital to group effectiveness in situations where a successful outcome for the entire group is the end result of numerous contributions or efforts by all group members (i.e., integration) and where successful contributions by one participant are contingent on a correct and timely contribution by another participant (i.e., temporal entrainment). Several operationalizations have been used to capture team coordination behavior. Assessments consistent with the conceptualization sketched above have focused on temporal response patterns and sequential analysis (Zalesny, Salas, & Prince, 1995), such as using observer ratings of communication patterns (Brannick, Roach, & Salas, 1993), measuring the amount of time one team member waits for another before engaging in a joint effort, and using Petri nets and artificial neural networks to model and analyze ongoing processes (Coovert, Campbell, Cannon-Bowers, & Salas, 1995). This last technique can graph the interactions of team members over time, determining the flow of activities, exchange, and communication.

Empirical research has established team coordination as an important correlate of team performance. For

example, Guastello and Guastello (1998) reported that coordination rules were implicitly learned and then transferred successfully to new rules of similar difficulty. They also noted that team coordination may occur without verbal mediation or leadership actions and that coordination transfer was less positive to a task of greater difficulty. Stout, Salas, and Carson (1994) examined the effects of coordination on two-person team performance on a flight simulation task. Interactive processes that were examined included such behaviors as providing information in advance, making long- and short-term plans, asking for input, assigning tasks, and stepping in to help others. Coordination ratings positively predicted mission performance of the team when individual task proficiency was held constant.

Important concerns relevant to future research on coordination center on issues of levels and time. With respect to levels, it is important to identify coordinated team responses that represent a broad range of disparate and complex patterns of individual action, and are not simply the sum of the responses of team members. Similarly, it is important to determine when the responses of individuals are part of a coordinated team response, and when they are simply individual responses (Zalesny et al., 1995). Finally, a key issue concerns how to represent interactions of individual team members over time at higher levels of analysis. Theoretical work on the nature of emergent constructs—how higher-level phenomena emerge from the characteristics and interactions of individuals—offers some guidance in this regard (Kozlowski & Klein, 2000). With respect to temporal issues, research must be sensitive to both the context and the temporal elements in which coordination occurs. Most theories assume that coordination is learned: How does it develop and emerge at the team level over time (Kozlowski et al., 1999)?

Cooperation can be defined as “the willful contribution of personal efforts to the completion of interdependent jobs” (Wagner, 1995, p. 152), and is often viewed as the opposite of conflict. Much of the research on cooperation and collaboration has been conducted in social psychology around issues of free riding and social loafing (Latané et al., 1979). This research has focused considerable energy on identifying factors that might eliminate uncooperative tendencies and instead induce cooperation in groups (Kerr & Bruun, 1983). We discuss such work elsewhere in the chapter in the section on Leadership and Motivation. Cooperation and collaboration have also been examined in the context of culture, specifically in the difference between individualistic and collectivistic orientations.

Research suggests that cooperation is generally associated with team effectiveness. For example, Wagner (1995) reported that individualists are less apt, and collectivists more apt, to behave cooperatively. He also found that individualism–collectivism moderates relationships between group size, identifiability, and cooperation such that group size and identifiability have greater effects on the cooperation of individualists than they do on the cooperation of collectivists. Seers, Petty, and Cashman (1995) found that departments with greater team-member exchange had significantly higher efficiency as captured from archival records. Pinto and Pinto (1990) examined the effect of cross-functional cooperation in hospital project teams and found that cooperation positively predicted both task and psychosocial outcomes, such that teams high in cooperation relied more heavily on informal modes of communication than did low cooperation teams. Finally, Smith et al. (1994) showed that cooperation in top management teams was positively related to return on investment and sales growth.

Most theoretical work that incorporates *communication* does so in the context of coordination and cooperation. That is, as noted previously, communication is seen as a means for enabling the more primary processes of coordination and cooperation. Communication can serve two important functions (Glickman et al., 1987) that aid taskwork and teamwork. Taskwork communication involves exchanging task-related information and developing team solutions to problems. Teamwork communication focuses on establishing patterns of interaction and enhancing their quality.

Research using content analysis has found that differences in communication patterns are related to differences in team performance (e.g., Foushee & Manos, 1981). Ancona and Caldwell (1992a, 1992b) found that external communication frequency was positively related to team performance. However, external communication was negatively associated with a team's assessment of its overall performance and with member ratings of team cohesion. Ancona (1990) reported that team leader strategies (e.g., probing) affected the types and frequency of external communication. Smith et al. (1994) reported that communication frequency was negatively related to TMT effectiveness, and suggested that greater communication frequency may be indicative of high levels of conflict. Campion et al. (1993) found that communication between teams did not have a significant impact on productivity, member satisfaction, or manager's judgments of team performance. Waller (1999) indicated that frequency of information collection (e.g., request

weather information) related to the performance of airline crews.

What are the compelling research issues for team communication? From our perspective, the *central* issue in team processes concerns the synergistic combination of individual contributions to team effectiveness. Communication is a primary means to enable more proximal factors like coordination and cooperation. Communication is a lens. Thus, research on communication type and frequency can be revealing of what team members are trying to coordinate and how much information they need or how difficult it is to do so. However, focusing solely on communication type and amount in the absence of attention to coordination and cooperation is incomplete. In addition, from a coordination perspective, focusing on just type and frequency ignores timing issues. When requests for information or assistance are made, how quickly others respond and the timing constraints imposed by the team task are likely to be critical issues in sorting out when communication is and is not helpful for team effectiveness.

The *Behavioral Process Taxonomy* developed by Marks et al. (2001) is a more highly differentiated conceptualization of team behavioral processes. It integrates related streams of prior research that sought to identify and classify behaviors that teams must execute to accomplish their task goals (Kozlowski & Ilgen, 2006). In the prior work, these behavioral action processes were described as team performance functions (Fleishman & Zaccaro, 1992) and team competencies (e.g., Cannon-Bowers, Tannenbaum, Salas, & Volpe, 1995; Salas & Cannon-Bowers, 1997), that is, as targets for training and skill development. It should be obvious, however, that this dual role is appropriate. Required behavioral actions for team effectiveness—performance functions—are key targets for training interventions—competencies (Kozlowski & Ilgen, 2006).

The conceptually elegant aspect of the Marks et al. (2001) conceptualization is that it imposed a dynamic, task episodic view of team tasks to identify when particular clusters of behavioral processes would be most relevant. They viewed task episodes as unfolding over time as sequences of transition (preparation) and action (engagement) that cycled across a series of ongoing phases. Using this temporal structure, they clustered processes that would be relevant for *transition* (i.e., mission analysis, goal specification, strategy formulation and planning), *action* (i.e., monitoring goal progress, systems monitoring, team monitoring and backup behavior, coordination), and *interpersonal relations* relevant across both phases

(i.e., conflict management, motivating and building confidence, affect management). The taxonomy represents a parsimonious integration of the prior research streams and helps to target *what, when, and why* particular team behavioral processes are likely to be most relevant.

Recently, meta-analytic research evaluated and extended the behavioral process taxonomy. Building on Marks et al. (2001), LePine, Piccolo, Jackson, Mathieu, and Saul (2008) proposed a hierarchical model structured so that the team behavioral processes formed first-order factors that loaded onto second-order transition, action, and interpersonal factors, all under the umbrella of an overarching team process factor. They conducted a meta-analytic confirmatory factor analysis (138 studies, 1,507 correlations, 147 independent samples) that supported this hierarchical organization of team behavioral processes. LePine et al. (2008) also assessed meta-analytic relationships between the first- and second-order processes and team performance, reporting significant associations with most in the range of 0.25 to in excess of 0.30.

The streams of prior research, parsimonious conceptualization, and solid support for the behavioral taxonomy dimensions (first-order factors) and the transition-action-interpersonal structure (second-order factors) makes the behavioral taxonomy a useful tool for conceptualizing and assessing team behavioral processes. Its roots—as team performance functions and competencies—are in use in the military, aviation, and space flight communities. Moreover, it has recently been extended to the medical community in their efforts to improve physician education, training, and team effectiveness (Fernandez, Kozlowski, Shapiro & Salas, 2008; Fernandez, Vozenilek, et al., 2008).

Finally, we should note that there is some new research attention (Mumford, Campion, & Morgeson, 2006) being applied to an enduring line of thinking about team member roles (Benne & Sheats, 1948) that is popular in practice circles (Belbin, 1993). The basic idea is that there are a certain set of “roles” that have to be fulfilled on a team in order for it to be effective (e.g., Stewart, Fulmer, & Barrick, 2005). Note that this approach differs from the competency, performance function, and behavioral taxonomy work we highlighted previously. Rather than viewing team skills and behaviors as being distributed across all team members, the role approach generally assumes that teams are more effective when critical roles are fulfilled by specific team members (i.e., the behaviors are clustered in different team members) (Belbin, 1981). Mumford et al. (2006) recently classified 120 roles they reviewed in the literature into 10 roles (i.e., contractor, creator,

contributor, completer, critic, cooperater, communicator, calibrator, consul, and coordinator) and developed a situational judgment test to assess role knowledge (Mumford, Van Iddekinge, Morgeson, & Campion, 2008). Their validation indicated that the team role test (TRT) was only weakly related to general cognitive ability and that it added incremental variance to the prediction of task and social role performance beyond ability and personality. These findings are promising. Note, however, that the TRT assesses role knowledge, and in that sense, is an alternative way to assess team member competencies or KSAs. It will be interesting to see to what extent the TRT captures unique variance beyond teamwork competencies and the extent to which it is uniquely predictive of team performance behaviors and team effectiveness. In addition, it will be useful to have a direct evaluation of the notion that concentrating team role behaviors in specific team members is better than having performance behaviors distributed across team members.

Enhancing Team Effectiveness

Team Competencies and Performance

The relevance of team processes to enhancing team effectiveness is that they are proximal predictors of team performance. Hence, although there are other strategies relevant for improving team effectiveness—such as influencing the composition of team abilities via selection, or improving processes via team design and leadership—direct enhancement of team processes via training is the most prevalent team effectiveness intervention (Cannon-Bowers & Salas, 1997). This strategy necessitates two foci: (a) specifying the competencies that underlie effective team performance and (b) designing and delivering training that improves the competencies, thereby enhancing team processes and increasing team effectiveness.

From a criterion perspective, team performance can be defined as a product or outcome of team action that satisfies external constituencies (Hackman, 1987). However, at the more specific level of identifying factors that constitute critical team performance dimensions definitional challenges are encountered. As noted in our discussion of team typologies, it is very difficult to develop a common specification of team performance—it varies by the type of team. Constraints emanating from the team’s context and its task, and their implications for internal and external linkages, lead to different dimensions of performance being relevant for different types of teams. Thus,

team performance specification and measurement must be grounded by the team context and task (Cannon-Bowers et al., 1995). Rigorous, reliable, and valid measures of team performance are essential tools for enhancing team effectiveness (Mathieu & Gilson, 2012).

It is also important to appreciate the orientation taken by researchers toward team performance in their efforts to enhance team effectiveness. The orientation has been much more targeted on performance processes, rather than performance outcomes, which can be influenced by many superfluous factors. Rather than treating team performance as a static, retrospective, summary variable intended to capture the outcome of many specific behaviors over an extended period of time, efforts to understand team performance for training purposes have tended to focus on what individuals and teams need to *do* to perform well. In other words, the focus has been on behaviors that have to be exhibited *over time* and on the underlying competencies that enable those behaviors. An important issue here is the need to distinguish between team-level performance outcomes, and the individual-level actions and interactions that are the foundation for team-level performance (Kozlowski, Brown, Weissbein, Cannon-Bowers, & Salas, 2000). In this regard, researchers have generally distinguished between taskwork skills—individual job or technical skills—and teamwork skills—KSAs that enable one to work effectively with others to achieve a common goal. Thus, at a general level, team performance and teamwork competencies are easy to identify—they are the cognitive, affective/motivational, and behavioral process mechanisms described previously and the KSAs that enable them, respectively. Three relatively comprehensive efforts to identify teamwork competencies are described below. This work forms the primary content of the Marks et al. (2001) behavioral process taxonomy described previously.

First, Fleishman and Zaccaro (1992) describe a taxonomy of team performance functions in an effort to be more specific than previous classifications of group performance tasks. They synthesized seven major categories of team performance functions: (a) orientation (e.g., information exchange regarding member resources and constraints); (b) resource distribution (e.g., load balancing of tasks by members); (c) timing (e.g., activity pacing); (d) response coordination (e.g., timing and coordination of responses); (e) motivation (e.g., balancing team orientation with individual competition); (f) systems monitoring (e.g., adjustment of team and member activities in response to errors and omissions); and (g) procedure maintenance (e.g., monitoring of general procedural-based activities). Note

that these performance functions primarily implicate competencies that enhance coordination and cooperation.

Second, based on their extensive work with aircraft cockpit crews and TDM teams, Salas, Cannon-Bowers, and their colleagues synthesized a set of eight teamwork skill dimensions (Cannon-Bowers et al., 1995; Salas & Cannon-Bowers, 1997):

1. Adaptability—competency to adjust strategies using compensatory behavior and reallocation of team resources.
2. Shared situational awareness—possession of shared/compatible mental models of the team's internal and external environment used to arrive at a common understanding of the team situation and to derive appropriate strategies to respond.
3. Performance monitoring and feedback—the capability to monitor teammate performance, give constructive feedback about errors, and make helpful suggestions for improvement.
4. Leadership/team management—competencies to plan, organize, direct, motivate, and assess teammates.
5. Interpersonal relations—skills to resolve conflict and engage cooperation.
6. Coordination—competencies to integrate and synchronize task activities with other teammates.
7. Communication—capability to clearly and accurately convey information and acknowledge its receipt.
8. Decision making—competencies to pool, integrate, and select appropriate alternatives and evaluate consequences.

In addition, they have also developed a typology for classifying team competencies and specifying essential knowledge (i.e., facts, concepts, relations), skills (i.e., cognitive-behavioral procedures), and attitudes (affective components of teamwork). The 2×2 typology is based on task and team dimensions. Each dimension is further distinguished by whether the competencies are specific or generic, resulting in four distinct classes of competencies appropriate for different types of teams. For example, *transportable competencies* (task and team generic) generalize across teams and are most appropriate for situations in which individuals are members of multiple project teams. In contrast, *context-driven competencies* (task and team specific) are appropriate for action teams with tight linkages to a dynamic external environment and complex internal workflows with a strong emphasis on coordination, knowledge of interlinked role demands, and adaptability (e.g., trauma teams, emergency response, TDM teams, aircrews). Specific competencies and KSAs

for each of the four cells can then be mapped for different types of teams (Salas & Cannon-Bowers, 1997).

Third, based on an extensive review, Stevens and Campion (1994) developed a *teamwork KSA* taxonomy of the skills underlying effective teamwork behavior. They concentrated on KSAs that were in line with traditional ability-based systems, as opposed to a personality orientation. They also selected attributes solely at the individual level of analysis because their focus was on selecting, training, and evaluating individuals for a team environment, not creating the best combination of team members. Finally, the authors rejected those KSAs that were team or task specific and instead focused on those skills related to the team and task generic component of the model proposed by Cannon-Bowers et al. (1995). Their search resulted in a final list of 10 interpersonal KSAs and 4 self-management KSAs. The interpersonal KSAs were classified further into conflict resolution, collaborative problem solving, and communication KSAs. The self-management KSAs were grouped into two categories: goal setting and performance management KSAs and planning and task coordination KSAs. Stevens and Campion (1999) subsequently developed a 35-item self-assessment of these teamwork KSAs and provided some supporting evidence for its validity, although their findings were mixed in that the teamwork KSA assessment was highly related to a traditional aptitude test and the validation did not replicate in a second sample.

Kozlowski and Ilgen (2006) encouraged further development and validation work. We echo that sentiment as subsequent research has tended to be, well, mixed. For example, in a study that used 42 student groups in an organizational simulation, Miller (2001) examined teamwork KSA scores aggregated to the team level, but did not find significant relationships with team performance. However, in a study that examined 57 ad-hoc student project teams, McClough and Rogelberg (2003) reported that the teamwork KSA measure predicted team member behavior assessed by external raters ($r = .31$) and team members ($r = 0.34$). However, this research did not assess the incremental validity of the teamwork KSAs, so it is difficult to determine whether it accounted for unique variance beyond that of traditional KSAs. Leach, Wall, Rogelberg, and Jackson (2005) found that teamwork KSAs mediated the relationship between team autonomy and performance and strain. The authors argue that autonomy allows a team to use their existing knowledge more effectively and to also learn new skills. Taking a different approach, Ellis, Bell, Ployhart, Hollenbeck, and Ilgen (2005) used the teamwork KSAs to guide skills training for 65 four-person action teams. Their findings indicated a number

of positive effects on cognitive and skill-based outcomes that accrued from the training. Although this does not offer direct support for the teamwork KSA assessment per se, it is supportive of the conceptual framework. There is other research that offers such indirect support as well (e.g., Hirschfeld, Jordan, Feild, Giles, & Armenakis, 2006). We encourage further efforts.

Team Training

A variety of direct, systematic training interventions have been proposed to improve team performance and effectiveness. We highlight a few techniques that have received research attention, but note that this is a huge area of practice—there are literally thousands of interventions. Because of the enormous human and material consequences of team failure, the aviation and military communities have pioneered efforts to improve team effectiveness through training. On the aviation side, some form of *Crew Resource Management* (CRM) training is in widespread use in both commercial and military aviation. Early CRM training focused on changing the teamwork attitudes of team members, whereas work in the 1990s shifted toward better definition, measurement, and training of team processes. On the military side, the TADMUS program developed and evaluated a variety of training techniques designed to improve the effectiveness of military teams (see Cannon-Bowers & Salas, 1998). Although these are distinctive areas of research, the tasks of aviation cockpit crews and tactical decision-making (TDM) teams share many underlying commonalities and, as a consequence, key processes essential for team effectiveness and methodologies to design and deliver training exhibit a high degree of overlap across both areas. Key processes are defined by the eight dimensions of teamwork (described previously; Salas & Cannon-Bowers, 1997).

Similarly, there is overlap in training techniques employed in both areas. Salas and Cannon-Bowers (1997), for example, identify six general training strategies for enhancing team processes and other essential KSAs: (1) task simulations—as a means to develop accurate performance expectations for various task demands, (2) role plays and behavior modeling—for building compatible KSAs, (3) team self-correction—in which team members monitor each other and provide corrective feedback, (4) team leader training—in which the leader guides the team through the self-correction process, (5) cross training—to instill crucial knowledge about the behavior and information needs of one's teammates, and (6) teamwork skill training—to provide generic teamwork skills when members must work on a variety of tasks or on many different teams. Research from TADMUS and

extensive work on CRM provide an empirical foundation supporting the efficacy of these techniques.

Moreover, there is meta-analytic support for the efficacy of team training techniques. For example, Salas et al. (2008) examined the effects of team training on team outcomes (i.e., cognitive, affective, process, and performance) and reported an overall corrected effect size of 0.34 (based on 1,563 teams and 52 effect sizes). Thus, team-training techniques evidenced positive effects, although the strongest effects were for process improvements relative to the other outcomes. In addition to *systematic training* techniques, some type of *team building* is perhaps the most ubiquitous form of “team training.” It generally focuses on improving skills in one or more of four areas (Salas, Rozell, Driskell, & Mullen, 1999): (a) goal setting—skills to set and achieve objectives; (b) interpersonal relations—skills to develop communication, supportiveness, and trust; (c) problem solving—skills for problem identification, solution generation, implementation, and evaluation; and (d) role clarification—skills to enhance understanding of others’ role requirements and responsibilities. Although there are many testimonials touting the effectiveness of team-building techniques, solid empirical support for their efficacy has been mixed. One meta-analysis (Salas et al., 1999) indicated no significant overall effect for team building on team performance. There was a small positive effect for subjective measures of performance, but no effect for objective indicators. And, of the four components, only role clarification evidenced any contribution to team performance. A more recent meta-analysis (Klein et al., 2009) reported an overall corrected correlation with team cognitive, affective, process, and performance outcomes of .31 (based on 579 teams and 26 effect sizes). Although this finding contrasts with the null findings (Salas et al., 1999), they are encouraging. However, given that the results are based on a small sample of studies, it would be encouraging if the pool of primary studies were larger. Clearly, more primary research is needed.

One thing that merits consideration is *when* team building is delivered. Although team building is oriented toward improving characteristics that emerge naturally during socialization and team development, team building as an intervention is typically targeted at mature teams that have already developed strong informal structures and normative behavior patterns. It is quite a bit more difficult to change informal structure once it has jelled than to shape it during socialization and development. Thus, we believe that team-building techniques may have more potential for leveraging improvement if applied when

team members are more malleable (Kozlowski, Gully, Salas, et al., 1996; Kozlowski et al., 1999).

Issues for Future Research on Team Training

We close this discussion on the use of training to enhance team effectiveness by identifying issues that need to be carefully considered in future research, organized around four themes: (a) what to train, (b) when to train, (c) how to train, and (d) at what level to train.

What to Train?

There was considerable progress in the 1990s on identifying important teamwork competencies and specifying their underlying KSAs. We note that virtually all of this work was conducted on action teams that place the most complex and challenging demands on teamwork skills. The big question that remains is to what extent do these competencies—presumably in some modified form—apply to other types of teams that have much weaker demands for temporal entrainment and coordination? Thus, a key research issue is the generality of the competencies to other team types. A related issue concerns the assessment of team performance. Many research assessments rely on extensive observation during complex simulations or in-context performance (see Brannick et al., 1993). However, assessing individual and team contributions to team effectiveness in organizational environments is plagued by all of the problems that beset individual-level performance appraisal. This area continues to be under researched.

When to Train?

As we noted previously, much team training is “remedial,” targeted on mature teams rather than during team socialization and development when team members are more malleable and training can exert more leverage. There are well-developed descriptive (Morgan et al., 1993) and normative (Kozlowski et al., 1999) models that specify developmental phases where particular competencies are likely to be most pertinent to trainees and more malleable to the influence of interventions. However, there has been relatively little research to examine the efficacy of shifting the target of training to track developmental progress. DeShon et al. (2001) provide promising evidence that shifting regulatory focus from individual to team contributes to enhanced team performance adaptability. We believe that this area represents a research issue with the potential for considerable practical gain.

How to Train?

The development and evaluation of new techniques will likely continue to capture the attention of many researchers and practitioners. Emerging technologies are making it increasingly possible to push team training out of the classroom and into the workplace, making it more contextually grounded and resolving the ever-present gap between training and skill transfer. With the increasing penetration of computers into the workplace, we will witness the growth of web-based training, distance and distributed training, distributed interactive simulations, and other tools that take advantage of increased computing power, low cost, and enhanced connectivity. However, it is important to remember that these new tools are merely delivery media. How to use these advanced tools to good instructional effect is the critical research issue (Bell & Kozlowski, 2010; Kozlowski & Bell, 2007; Kozlowski et al., 2001).

What Level to Train?

A final issue concerns the level at which training should be delivered—individuals or intact teams? Much “team” training is really targeted on individual skill building. Can individual training improve team effectiveness? Focusing on the issue of *vertical transfer* (i.e., the extent to which individual actions propagate upwards to influence team performance), Kozlowski and colleagues (Kozlowski & Salas, 1997; Kozlowski et al., 2000) have argued that the nature of the teams’ task should dictate the mode of delivery, individual or team. When team-level performance is based on *compilation* processes—workflows that emphasize distributed expertise, temporal entrainment, and synchronous coordination—training should be delivered to intact teams in actual performance settings (or very close approximations) because of the emphasis on integrating disparate actions. In contrast, when team-level performance is based on *composition* processes—workflows that emphasize additive individual contributions—training should be targeted at the individual-level because it is more efficient and cost effective. Research on this issue is virtually nonexistent, and represents an opportunity to refine team training delivery models.

TEAM LEADERSHIP AND MOTIVATION**Leadership in Teams**

Most models of team effectiveness recognize the critical role of team leaders. Although there is certainly no

shortage of leadership theories, examining this extensive literature is beyond the scope of this chapter (see Day, 2012, for a comprehensive review). At the onset we note that most organizational leadership theories are generic in their focus, whereas team leadership provides a context and a unit focus. The key question is: *What should leaders do to enhance team effectiveness?* This focuses attention on the leader’s functional role within the team. In addition, many organizational leadership theories focus on the individual level; there are relatively few attempts to examine the differences between leading in the team context and leading individuals. In this section, we examine the functional role of team leaders and discuss how leadership functions can be distributed to team members through self-management and shared leadership. We conclude with practical recommendations for leading teams.

Functional Role of Team Leaders

There have been several efforts to specify the functional role of team leaders, and there is reasonable consistency in the important leadership functions that need to be accomplished. Different labels have been used to describe these functions, but they can be grouped into two broad categories: (a) the development and shaping of team processes, and (b) the monitoring and management of ongoing team performance (Fleishman et al., 1991; Hackman & Walton, 1986; Komaki, Desselles, & Bowman, 1989; Kozlowski, Gully, McHugh, et al., 1996; Kozlowski, Gully, Salas, et al., 1996; Kozlowski, Watola, Jensen, Kim, & Botero, 2009; McGrath, 1962). Recent meta-analytic support for these broad categories of team leadership functions and their relevance to team effectiveness is provided by Burke, Stagl, Klein, Goodwin, Salas, & Halpin (2006).

With respect to team development, leaders are often faced with the challenge of building a new team. In these situations, a leader’s functional role is to develop individuals into a coherent, seamless, and well-integrated work unit (Kozlowski, Gully, McHugh, et al., 1996). In other instances, teams experience personnel outflows and inflows over time. As new replacement personnel are brought into the team, they need to be socialized and assimilated (Moreland & Levine, 1989). Leaders are critical to this newcomer assimilation process (Chen, 2005; Ostroff & Kozlowski, 1992). Developmental functions of team leaders focus on the enactment of *team orientation* and coaching to establish *team coherence* (Kozlowski, Gully, McHugh, et al., 1996). Team orientation includes factors with motivational implications, such as promoting shared goal commitment, creating positive affect, and

shaping climate perceptions. Team coherence includes the development of linked individual goals, a repertoire of team task strategies, and compatible team member role expectations. The leader's developmental role is to establish and maintain coherence and integration among the members of the unit. Coherence then allows team members to self-manage during periods of intense task engagement.

A second major functional role of team leaders is to establish and maintain favorable performance conditions for the team. In this capacity, leaders engage in two types of behavior: monitoring and taking action (Hackman & Walton, 1986; Kozlowski, Gully, McHugh, et al., 1996; McGrath, 1962). Monitoring involves obtaining and interpreting data about performance conditions and events that might affect them. Monitoring functions include vigilance, diagnosing group deficiencies, data gathering skills, forecasting impending environmental changes, and information use in problem solving. For example, an effective leader will monitor whether the team has adequate material resources and will also forecast potential resource crises. Leaders also need to collect performance information and provide feedback. In doing so, they make team members aware of the consequences of their behaviors. When problems are discovered, leaders must gather information to determine the nature of the problem and take action to devise and implement effective solutions. A leader's actions can be designed to improve the present state of affairs, to exploit existing opportunities, or to head off impending problems. Specific actions can include clarifying the direction of the team, strengthening the design of the group or its contextual supports, providing coaching or process assistance, or ensuring the group has adequate resources (Fleishman et al., 1991; Hackman & Walton, 1986; Komaki et al., 1989; Kozlowski, Gully, McHugh, et al., 1996; McGrath, 1962).

One important characteristic underlying these efforts to identify the key functional roles of team leaders is the assumption that the leader typically interacts directly with team members in the processes of team development and performance management. However, this assumption may not always hold true, especially with today's advanced technologies and the capability to have virtual teams composed of members who are spatially and temporally distributed. As Bell and Kozlowski (2002) highlighted, virtual environments create challenges for team leaders in that they have to develop structures to substitute for direct leadership influence and they have to promote shared leadership whereby team members accomplish some leadership functions (Kirkman et al., in press). This idea of

distributing and sharing leadership functions among team members (Pearce & Conger, 2003) has gained traction over the last decade. For example, Klein, Ziegert, Knight, and Xiao (2007) described how the formal team leader in shock-trauma emergency room teams dynamically delegated leadership functions to novice team members as a way to accomplish team goals and build novice skills. Similarly, Kozlowski et al. (2009) incorporated the concept of shared leadership in their model of dynamic leadership and team adaptation. Shared leadership was seen as a target for team development as a key aspect of facilitating team adaptation to unexpected challenges.

Recently, Morgeson, DeRue, and Karam (2010) developed a comprehensive taxonomy of team leadership functions. They take a broad perspective on team leadership, viewing it with respect to differences in formality (formal vs. informal) and locus (internal vs. external). Thus, leadership functions can be accomplished by a variety of sources—a traditional, hierarchical team leader (formal, internal), an advisor (formal, external), shared leadership by team members (informal, internal), and a champion (informal, external). To create the taxonomy, they first reviewed 85 relevant conceptual and empirical sources focused on team leadership, supplemented by traditional leadership research and the team effectiveness literatures, and compiled 517 leadership behaviors. They then used a bottom-up approach to cluster the behaviors into 15 categories, which they further clustered into transition and action phase activities (Marks et al., 2001). Transition functions include: compose team, define mission, establish expectations and goals, structure and plan, train and develop team, sense making, and provide feedback; action functions include: monitor team, manage team boundaries, challenge team, perform team task, solve problems, provide resources, encourage team self-management, and support social climate (Morgeson et al., 2010, p. 10). In addition, they also refined the behaviors into a concise set of indicators for each of the 15 team leadership functions as a way to promote future research on the role of leadership functions in the promotion of team effectiveness.

Self-Managing Teams and Shared Team Leadership

Teams described as self-managing have several defining characteristics. They are given relatively whole work tasks and are allowed increased autonomy and control over their work (Hackman, 1986; Manz, 1992). In addition, the members of such teams are responsible for many traditional management functions, such as assigning members to various tasks, solving within-team quality and interpersonal problems, and conducting team meetings (Lawler,

1986). Self-managing teams often have leaders; however, their primary function is to enable self-management.

Many benefits have been attributed to self-managing teams, including increased productivity, quality, and improved quality of work life for employees, as well as decreased absenteeism and turnover (Cohen & Ledford, 1994; Lawler, 1986; Manz & Sims, 1987). Although research suggests that self-managing work teams can be quite effective (Neck, Stewart, & Manz, 1996; U.S. Department of Labor, 1993), they sometimes fail. It has been suggested that these failures are often linked to the behaviors of team leaders. For example, teams with leaders who are too actively involved in the team's activities or who are too autocratic may not develop a sense of autonomy and may feel powerless (Stewart & Manz, 1995). It has been suggested that the optimal leader for self-managing teams is one who displays passive involvement in the team's activities and a democratic power orientation. Such leaders lead through modeling and assisting, helping the team to develop self-direction and ownership for activities. Yet, a recent study by Morgeson (2005) found that more active forms of intervention by external leaders were positively related to team perceptions of leader effectiveness as the events experienced by self-managing teams became more disruptive. These findings suggest that the appropriate role of external leaders in self-managing teams may need to be guided by joint consideration of the events that occur in the team context (e.g., novelty, potential for disruption) as well as the team's ability to handle the events.

Research has highlighted additional contextual factors that may moderate the effectiveness of self-managing teams. For example, Tesluk, Kirkman, and Cordery (2001) found that self-leadership resulted in greater autonomy in work units that displayed a less cynical orientation toward change efforts. In work groups that had a more cynical attitude toward change efforts, a self-leadership management style had little impact on perceptions of team autonomy. Kirkman and Shapiro (2001) found that cultural values, such as power distance and doing orientation, predicted resistance to self-management, and that these cultural values played a stronger role in creating resistance in some countries (e.g., United States and Belgium) than in others (e.g., Finland and Philippines). Langfred (2004) provides some evidence that high levels of trust combined with high levels of individual autonomy can prevent the members of self-managing teams from monitoring one another, which can ultimately lead to a performance loss. Stewart and Barrick (2000) found that for teams engaged primarily in conceptual tasks, team

self-leadership exhibited a positive relationship with performance. In contrast, for teams engaged primarily in behavioral tasks, there was a negative relationship between self-leadership and performance. However, the mechanisms underlying these differential effects were unclear and should be examined in future work.

As we noted previously, one emerging trend in the team leadership area is the idea that leadership functions can be distributed to, and shared by, team members. This concept is distinct from self-managing teams, as there may often be a formal, internal leader in place (Day, 2012; Klein et al., 2007; Kozlowski et al., 2009; Morgeson et al., 2010); for shared leadership, responsibility for accomplishing leadership functions is dynamically shared among members and with a team leader. The concept of shared leadership, although generally applicable as a supplement to hierarchical leadership (Day, 2012), has received attention as a way to help bolster the effects of hierarchical leadership in virtual teams where the impact of traditional leader behaviors may be mitigated by the challenges of space distance, time differences, and asynchronous electronic communication (Bell & Kozlowski, 2002). For example, Hoch (in press) has developed a model of distributed team leadership for virtual teams that views shared leadership as a key adjunct to support traditional hierarchical leadership. Carte, Chidambaram, and Becker (2006) showed that high-performing virtual teams evidenced more shared leadership behavior focused on team monitoring relative to less effective teams.

Although the underlying mechanisms are not clear, one likely possibility is that shared leadership promotes a sense of psychological empowerment that motivates the team. Although psychological empowerment—autonomy, meaning, competence, and impact—is conceptualized at the individual level of analysis (Spreitzer, 2008), several researchers have argued that it can emerge as a shared team-level property with motivational implications for team performance (e.g., Chen, Kirkman, Kanfer, Allen, & Rosen, 2007; Chen & Tesluk, 2012; Kirkman & Rosen, 1999). Indeed, Kirkman, Rosen, Tesluk, and Gibson (2004) showed that team empowerment was more important for teams that were more (vs. less) virtual in terms of promoting process improvement and customer satisfaction. Also, Chen, Sharma, Edinger, Shapiro, and Farh (2011) showed that the team-level stimuli of empowering leadership had a cross-level influence on members' psychological empowerment, which mediated the relationship between empowering leadership and several individual outcomes (e.g., turnover intentions, innovative behavior). Thus, although there are likely several mechanisms

for the influence of shared leadership on team effectiveness through leadership functions, there is also likely to be a motivational pathway mediated by team empowerment.

Practical Applications

Research and theory on leadership have been conducted at multiple levels of analysis. While some theories focus on specific characteristics of leaders or their followers (e.g., Bass, 1981), other theories, such as leader–member exchange (LMX), focus on the dyadic relationships between a leader and a member (e.g., Dansereau, Graen, & Haga, 1975), and still other theories focus specifically on leadership in team contexts (e.g., Hackman & Walton, 1986; Kozlowski, Gully, McHugh, et al., 1996; Kozlowski et al., 2009; Morgeson et al., 2010). Although the focal level differs across these theories, many of them provide recommendations that are presumed to be applicable in team settings. Indeed, many of the leader characteristics (e.g. intellectual stimulation, consideration) and leader–member exchange patterns (e.g., delegation) that have been shown to be effective in leading individuals should also be effective for leading individuals in the team context.

It is important, however, to recognize that team environments create a number of unique challenges for leaders. For example, team leaders must focus not only on developing individual skills but also on promoting the development of teamwork skills that underlie coordination, such as mutual performance monitoring, error detection, load balancing, and resource sharing (Kozlowski, Gully, McHugh, et al., 1996). Team leaders also must guide the development of a collective, team-level efficacy, or the belief that the team can work together effectively to accomplish the task or goals set before it (Campion et al., 1993; Shea & Guzzo, 1987). Team leaders can also be instrumental in developing effective team mental models (Klimoski & Mohammed, 1994). Marks et al. (2000), for example, found that leader briefings that highlighted task strategies affected the development of team mental models, which in turn positively influenced team communication processes and team performance.

It is also important for team leaders to tailor their behavior based on the team's environment and task. The research discussed above by Stewart and Barrick (2000) and Morgeson (2005), for example, suggests that leaders should promote different levels of self-leadership depending on the team's task. Pearce (2004) provides a practical examination of the conditions under which leadership is most appropriately shared in teams, the organizational systems that can be used to facilitate the development of

shared leadership, and strategies for effectively combining vertical and shared leadership. Leaders may also need to adopt a different role when faced with the challenge of leading a virtual team. In these situations, it is often very difficult for leaders to monitor the performance of team members due to spatial and temporal separation. As a result, it may be critical for virtual team leaders to clearly define the team's objective, facilitate team members' understanding of their responsibilities, promote distributed and shared team leadership, and create explicit structures that help the team manage its performance (Bell & Kozlowski, 2002).

Team Motivation

The majority of theory and research on motivation has been focused at the individual level. In fact, relatively little research has specifically examined motivation as it operates in team contexts or at the team level. Much of what we know about motivation in team contexts comes from research in the field of social psychology that has examined the productivity or process loss that often occurs when individuals work in groups. Although much of this work focuses on individual motivation and performance in the group context—not on team motivation and performance per se, researchers frequently extrapolate effects to the team level. Moreover, as we discuss below, many of these findings may not apply to teams as they typically exist in organizational settings, suggesting that researchers need to focus greater attention on the issue of motivation in work teams. In the following section, we provide a brief review of research on productivity loss in teams. We then examine some theories that have focused specifically on motivation in teams, and conclude with practical recommendations for motivating teams.

Productivity Loss

A large body of research has shown that individuals tend to exert less effort when their efforts are combined rather than individual. This effect, referred to as social loafing, and similar phenomena (e.g., free-rider and sucker effects) are considered to be robust and to generalize across tasks and work populations (Karau & Williams, 1993). However, research has also shown that there are numerous variables that moderate the tendency to engage in social loafing. For example, social loafing can be eliminated by having individuals work with close friends, increasing the identifiability of individual contributions, and providing clear performance standards. In fact, research suggests that many of the variables that eliminate social loafing also

serve to enhance team performance. This effect is known as social facilitation, which results from the motivation to maintain a positive self-image in the presence of others (Bond & Titus, 1983; Zajonc, 1965).

Research on social loafing and on social facilitation have developed independently and offer rather conflicting views on the motivational effects of individuals working in teams. This apparent discrepancy, however, may be explained by the fact that traditional research on social loafing has often been conducted in artificial groups that do not conform with the definition of groups as involving individuals' mutual awareness and potential mutual interaction (McGrath, 1984). These studies have typically used pooled tasks in which team members provide independent and unidentifiable contributions to the team's performance. More recent research, however, has found that characteristics of teams in work organizations, such as team member familiarity, interaction, and communication, eliminate social loafing and may actually lead to social facilitation (Erez & Somech, 1996). Thus, the extent to which social loafing and related effects are important motivational phenomena in the context of work teams is open to question.

Theories of Team Motivation

Compared to research on individual-level motivation, relatively little work has directly considered the issue of motivation in teams. One of the earliest efforts to explore motivation in teams is represented by research on group goal setting, which focused on extending well-established findings at the individual level to the team level. An early meta-analysis by O'Leary-Kelly, Martocchio, and Frink (1994) found a strong group goal effect, such that groups that had goals performed almost one standard deviation higher than groups that did not have goals. A more recent meta-analysis by Kleingeld, van Mierlo, and Arends (2011) was able to use a larger pool of studies to examine potential moderators of group goal setting effects. The results again revealed a positive, albeit somewhat smaller, overall effect of group goals on group performance ($d = 0.56 \pm 0.19$, $k = 49$). In addition, specific-difficult group goals were found to relate to higher performance than nonspecific goals ($d = 0.80 \pm 0.35$, $k = 23$). Group-oriented goals (i.e., focused on the individual's contribution to group performance) had a positive effect on group performance ($d = 1.20 \pm 1.03$, $k = 4$), but individually oriented goals (i.e., focused on individual performance) had a negative effect on group performance ($d = -1.75 \pm 0.60$, $k = 6$). Surprisingly, task interdependence, complexity, and participation failed to moderate

the effect of group goals. Although these findings provide further evidence that the central tenets of goal setting generalize to the team level, future work is needed to better understand the contingencies of group goal setting effects. For instance, group goal setting research has not examined how goal content (i.e., learning vs. performance) influences team performance (Kozlowski & Bell, 2006), nor has much of this research considered how individual- and team-level feedback shape team learning and performance (DeShon et al., 2004).

More recent research focused on action regulation, however, has begun to examine the dynamic interplay among key components of the broader regulatory process (e.g., goals, commitment, strategies, effort, performance, feedback, comparison, and reactions) across the individual and team levels of analysis. Consistent with the critical conceptual issues we highlight in this chapter, models that focus on action regulation emphasize the dynamics of the process as it unfolds over time and the multilevel and emergent aspects of team regulation (Bell et al., 2012). DeShon et al. (2004), for instance, proposed and tested a multiple-goal, multilevel model of individual and team regulation, which featured parallel individual and team regulatory processes. Their results provided support for the homologous multilevel model, thereby suggesting that the processes of action regulation that guide individual resource allocation, learning, and performance extend to the team level. Chen, Thomas, and Wallace (2005) conducted a multilevel examination of the relationships among training outcomes, regulation processes, and adaptive performance at the individual and team levels. Although the results indicated both similar and different patterns of relationships across levels of analysis, the study provides further evidence for parallel regulation constructs and processes at the individual and team levels. Although these studies provided a valuable integration of theories of individual and team motivation, the focus on parallelism created a gap in understanding the cross-level interplay between individual and team regulation. Guided by Chen and Kanfer's (2006) theoretical model of motivation in teams, Chen et al. (2009) focused on examining these cross-level linkages. Based on a reanalysis of the data from the two studies described above, the authors provide support for the hypothesized linkages across the levels of regulation system and emphasize the importance of the team context in shaping individual regulatory processes and outcomes. Overall, we believe the multilevel model of action regulation holds great promise for guiding future research and integrating and interpreting relevant research findings.

Practical Recommendations

Several authors have offered recommendations for enhancing team motivation. Sheppard (1993), for example, suggested that lost productivity can arise in teams when any one of the following three conditions is present: individuals perceive no value to contributing, perceive no contingency between their contributions and achieving a desirable outcome, or perceive the costs of contributing to be excessive. To overcome these effects, Sheppard provided three categories of solutions that correspond to each of the three sources of productivity loss. These include providing incentives for contributing, making contributions indispensable, and decreasing the costs associated with contributing, respectively. The Productivity Measurement and Enhancement System (ProMES; Pritchard, Jones, Roth, Stuebing, & Ekeberg, 1988) is a concrete example of how group-based feedback, goal setting, and incentives can be used to reduce productivity loss and enhance team performance. A recent meta-analysis of 83 ProMES implementations reported substantial, and often sustained, effects of ProMES on productivity improvements across a wide range of organizations and different team tasks (Pritchard, Harrell, DiazGrandos, & Guzman, 2008).

Rewards and incentives, examined mainly in service teams, are among the most frequently studied factors designed to enhance team motivation in organizations. Effects for rewards have been mixed. Several studies have found that rewards have no significant relationship with team effectiveness (e.g., Campion et al., 1993; Gladstein, 1984), although a few studies have found rewards to have positive effects under certain conditions (Wageman, 1997). Wageman (1995) found that service technician groups with low task interdependence performed best with individual-based rewards, but groups with high interdependence performed best with group-based rewards. Pritchard and colleagues (1988) also found that incentives lead to a small increase in team productivity, although their ProMES intervention produced more substantial increases. Cohen, Ledford, and Spreitzer (1996) found that a nonmonetary reward, recognition by management, was positively associated with team ratings of performance, trust in management, organizational commitment, and satisfaction for both self-directed and traditionally managed groups in a telecommunications company. Finally, Pearsall, Christian, and Ellis (2010) found that teams operating under a hybrid reward system outperformed teams operating under individual or shared reward systems, and that the benefits of hybrid rewards were due to improvements in information allocation and reductions

in social loafing. Overall, there is some evidence to suggest that group-based rewards can increase team effectiveness. However, research is needed to further examine the role of contingency variables, such as task structure and team composition, in the relationship between reward systems and work team effectiveness (DeMatteo, Eby, & Sundstrom, 1998).

Swezey and Salas (1992) conducted a review of research on individuals within teams or groups and identified several prescriptive guidelines that have relevance to team motivation. They offered several concrete suggestions for motivating teams, such as employing positive reinforcement techniques and developing a system of rewards for those who exhibit supportive behaviors toward teammates. Research has tended to show that team performance is enhanced when goals, feedback, rewards, and task interdependence requirements are congruent with one another (Saavedra, Early, & Van Dyne, 1993; Weaver, Bowers, Salas, & Cannon-Bowers, 1997). Thus, to enhance team motivation, an organization should ensure that the work context is configured so that individual and team motivation are aligned and do not contradict each other.

CONTINUANCE AND DECLINE**Team Viability**

Team effectiveness has often been defined as the quantity and quality of a team's outputs (e.g., Shea & Guzzo, 1987). This definition, however, overlooks the possibility that a team can "burn itself up" through unresolved conflict or divisive interaction, leaving members unwilling to continue working together (Hackman, 1987, p. 323). Thus, some researchers have argued that definitions of team effectiveness should also incorporate measures of team viability (Guzzo & Dickson, 1996; Sundstrom et al., 1990). Team viability refers to members' satisfaction, participation, and willingness to continue working together in the future. It can also include outcomes indicative of team maturity, such as cohesion, coordination, effective communication and problem-solving, and clear norms and roles (Sundstrom et al., 1990). The major issue, however, is whether a team can sustain effective levels of performance over time.

Relatively little is known about long-term team viability, although theory (Katz, 1980) suggests that team continuance has a curvilinear relationship with team performance: team effectiveness initially improves with time,

but declines with increasing group age. Katz (1982) suggests that decline begins two to three years into a team's existence. Research on R&D teams suggests that effectiveness peaks between 2–3 (Katz & Allen, 1988) and 4–5 years of group age (Pelz & Andrews, 1966), with marked decline after 5 years (Katz & Allen, 1988). Other work suggests decline as quickly as within 16 months of group existence (Shepard, 1956). While the mechanisms that cause team performance to fade over time are not well understood, several explanations have been offered. Hackman (1992) suggests that the increased cohesiveness that develops over time may lead to groupthink and other negative outcomes associated with the rejection of dissenting opinions. Continuance also tends to increase team member familiarity. It has been argued that familiarity may be beneficial early in a team's existence, by fostering rapid coordination and integration of team members' efforts (Cannon-Bowers et al., 1995). However, familiarity may eventually become a liability as the lack of membership change contributes to stultification and entropy (Guzzo & Dickson, 1996). Similarly, Katz (1982) has suggested that communication within and between teams declines as teams age. Katz and Allen (1988), who examined 50 R&D teams, provided support, showing that declines in communication were associated with effectiveness declines over time. Importantly, they also reported that the greatest communication decay was in those areas most central to team activities (e.g., for technical service teams, intrateam communication; for project teams, external communication). Thus, team communication appears to be an important mediator of the effects of team continuance on team effectiveness.

One area where this issue of ongoing viability is a concern is with the emerging interest in reviving space exploration outside of the confines of near-Earth orbit. Space flight teams operate in isolated, confined, and extreme (ICE) environments. The near-Earth orbit habitat of the International Space Station (ISS) is an ICE setting, but astronauts have near-continuous interaction with ground controllers, an extensive personal support network (i.e., communication with family, personal counselors, etc.), and even some of the comforts of home (i.e., packages from home when supplies arrive). Mission durations generally range from 6 months to a year, with the longest mission being 438 days by the Russian cosmonaut, Valeri Polyakov. However, long-duration missions to distant asteroids or Mars will be an altogether different sort of experience, with many new challenges due to the vast distance: long communication lags, need for more autonomous crew operations, social separation

from family and friends. Thus, long-duration space missions will involve extreme ICE contexts. Much more basic research is needed to examine team viability (i.e., the maintenance of supportive team processes and effectiveness) over significant periods of time and to identify factors that can promote it, maintain it, and restore it (Braun et al., 2011; Pearce et al., 2011).

Recommendations for Enhancing Team Viability

Although research suggests that team performance deteriorates given enough time, it may be possible to combat this trend. West and Anderson (1996) show that four factors—vision, participative safety, task orientation, and support for innovation—define a climate that predicts team innovativeness. It is also important for organizations to assess whether a group is using the energy and talents of its members well (rather than wasting or misapplying them), and to determine whether group interaction patterns that develop over time expand (rather than diminish) members' performance capabilities. For example, it has been suggested that while cohesion is detrimental when it is social or interpersonal in nature, it may be beneficial when it is task-focused (Hackman, 1992). Team goals and rewards may be used to facilitate task-based cohesion (Zaccaro & Lowe, 1988), or interventions may be developed to maintain team communication over time.

Teams should also be provided ongoing assistance throughout their life cycle. Hackman (1987) suggests that this assistance can come in three forms. First, teams can be provided opportunities to renegotiate aspects of their performance situation. Second, process assistance should be provided as needed to promote positive group synergy. For example, it may be important to manage personnel inflows and outflows over the course of a team's life cycle. Just as stable membership can lead to dullness and entropy, the introduction of new members—properly managed—can renew and revitalize a team. And, third, teams should be provided opportunities to learn from their experiences.

Finally, it may be possible to influence team viability through the selection of team members. Barrick et al. (1998) found that teams that have greater cognitive ability, are more extraverted, and are more emotionally stable are more likely to stay together in the future. They also found that the effects of extraversion and emotional stability on team viability were mediated by social cohesion. Teams that were more extraverted and emotionally stable had more positive group interactions, thus becoming more socially cohesive, which in turn enhanced the team's capability to maintain itself (Barrick et al., 1998). Clearly,

the issue of team viability can benefit from additional research attention.

RESEARCH ISSUES AND RECOMMENDATIONS

At the beginning of this chapter, we noted that there was a rapidly expanding wealth of research on work groups and teams in organizations. We have endeavored to capture the essence of the most relevant material in this review, and have identified a multitude of issues in need of research attention. In this final section, we highlight what we regard as the major issues that ought to shape future work in the area. We begin with a reconsideration of our four themes—*context*, *workflow*, *levels*, and *time*—to provide a framework for a discussion of general theory and research issues. We then close with more specific recommendations for new research organized around the major topics addressed in the review. Recommended research targets are compiled in Table 17.3.

Research Issues

Context

One of the key distinguishing characteristics of the organizational perspective on work groups and teams is appreciation of the fact that they are embedded in a broader system that sets constraints and influences team processes and outcomes. Yet, as one looks across this literature, it is clear that the effects of top-down, higher level contextual factors on team functioning are neglected research issues. The importance of contextual influences is explicitly recognized theoretically—virtually every model of team effectiveness incorporates organizational contextual factors—yet context is not well represented in research. Beyond theoretical influences, we know relatively little about the effects of the organizational context or broader system linkages on team functioning.

Context is also relevant as a product of bottom-up processes. That is, individual team members—by virtue of their cognition, affect, behavior, and mutual interaction processes—enact structural features (e.g., norms, expectations, informal roles) that serve as team-generated contextual constraints. Again, contextual enactment is well represented in theory, but represents just a small portion of the research base. For example, the strong influence of normative expectations on team functioning is an accepted truism in the literature, but knowledge of how such expectations develop is sketchy. There is relatively little work

TABLE 17.3 Team Effectiveness Research Targets

Research Issues

Context

Team research needs to incorporate the effects of major organizational context factors and linkages specified in models of team effectiveness.

Workflow

Theorists and researchers need to be more sensitive to external influence on task interdependencies and to the dynamics and variations of task interdependencies over time.

Levels

Research on team phenomena must be cognizant of and consistent with the principles of multilevel theory, data, and analyses.

Time

Team theory and research should explicitly address the implications of time for team phenomena.

Good, solid, basic descriptive research on important team temporal phenomena is encouraged.

Research Recommendations

The Nature of Teams

Research should focus on delineating the dimensions that differentiate teams rather than on characterizing different “types” of teams.

Composition

Research is needed to better integrate team composition, member demography, and configural (e.g., faultlines, cultural mosaic) approaches.

Formation, Socialization, and Development

Research is needed on work team socialization.

Research is needed to describe, validate, compare, and extend models of work team development.

Team Effectiveness, Processes, and Enhancements

Research on team cognition needs to explicitly distinguish team learning processes and team knowledge outcomes.

Research on team affective/motivational mechanisms needs to focus on construct formation, emergence, and dynamics.

Research on team behavioral mechanisms should focus on the behavioral process taxonomy, incorporate communication behavior, and more precisely target the level of team training.

Leadership and Motivation

Research to refine and extend team-centric functional leadership theory is encouraged.

Research to refine and extend multilevel regulatory theory—its emergence, homology, cross-level interplay, and dynamics—on team learning, motivation, and performance is encouraged.

Continuance and Decline

Research is needed on the effects of team member longevity on team functioning, productivity, and innovation.

examining the formation of these bottom-up constraints (e.g., Bettenhausen & Murnighan, 1985). This is also true of the many “team processes” or “emergent states” (e.g., climate, team mental models, cohesion, team efficacy, etc.) that we reviewed. The literature is not informative as to how they form and emerge, bottom up over time (Kozlowski, 2012; Kozlowski & Chao, 2012b).

We think that the field’s relative lack of knowledge in this area is due in part to the prevalence of laboratory research on team effectiveness. This observation is not intended as a criticism of laboratory research on teams per se. Appropriately targeted to precisely decompose processes, laboratory research has and will continue to contribute much to our understanding of team functioning. However, it must be acknowledged that laboratory research, because of its synthetic nature, can contribute to our understanding of contextual influences in only very limited ways. Decomposing the effects of context is really the province of field research with its access to contextually rich research settings. Unfortunately, when contextual effects have been examined in field research on teams, there has been a tendency to focus on the effects of indirect support factors as opposed to more direct linkages to the organizational system. In other words, research has tended to conceptualize team contextual factors in terms of the provision of training or availability of rewards (e.g., Cohen & Bailey, 1997), which we would expect to be supportive of team functioning, instead of direct system linkages such as technology, structure, and other factors relevant to workflow input–output linkages. Yet, it is these latter factors that are most likely to operate as major constraints on team structure and process. One challenge in extending our understanding of the context is the tendency for research to be conducted in single organizational settings. Researchers have to endeavor to gain access to settings that vary on important contextual factors.

Team research needs to incorporate the effects of major organizational context factors and linkages specified in models of team effectiveness.

Workflow

Recognition of the central importance of the team workflow, and the task interdependence it entails, to team structure and process is a second key characteristic of the organizational perspective on work groups and teams. For the most part, this appreciation is reasonably well represented in both theory and research that generally regard task interdependence either as a critical boundary condition or a moderator of effects (Saavendra et al., 1993; Wageman, 1999). Given its demonstrated importance, new

research that fails to acknowledge the effects of task interdependence for the team phenomenon in question has little relevance to building knowledge in the work groups and teams literature. It is a feature that should be explicitly addressed—either as a boundary condition or a moderator—in all research on work groups and teams.

We applaud the general recognition of the importance of task interdependence, but assert that this focus only gets at half of the problem—intra-team linkages. We believe that research also has to attend to external system linkages, and how the interface with relevant external factors affects intra-team linkages. In other words, external linkages to broader contextual demands such as temporal paces (deadlines) and the degree of coupling to the context influence team internal interdependences (see Figure 17.2). Moreover, task demands and related interdependencies are not necessarily steady states. Tasks can be conceptualized as episodic (Marks et al., 2001) and cyclical (Kozlowski, Gully, McHugh, et al., 1996; Kozlowski, Gully, Salas, et al., 1996), making the nature and form of internal interdependencies dynamic and unpredictable (Kozlowski et al., 1999). With appropriate research design and data, there are opportunities to apply sophisticated dynamic modeling techniques (DeShon, 2012) and network science (Brass, 2012) to help us extract more understanding of these dynamics.

Theorists and researchers need to be more sensitive to external influence on task interdependencies and to the dynamics and variations of task interdependencies over time.

Levels

Teams are composed of individuals and are embedded in a nested organizational systems structure. Teams per se do not think, feel, or behave; individuals do, but individuals think, feel, and behave in an interactive context that can shape their cognition, affect, and behavior such that it has emergent collective properties. These emergent properties evolve over time and are further constrained by higher-level contextual factors. A key implication of this organizational systems conceptualization is that team function and process must be regarded as multilevel phenomena (Kozlowski & Klein, 2000).

A multilevel conceptualization of team phenomena means that theory and construct definition, measurement procedures, and data analyses must be consistent with principles drawn from the levels of analysis perspective (Kozlowski & Klein, 2000). A levels perspective necessitates that constructs, data, and analyses be *aligned* with the level to which conclusions are to be drawn. For much

of the research in this area, that level is the team. Yet, many studies that draw generalizations to the team level assess data or conduct analyses at the individual level. Such generalizations are flawed. In other instances, studies assess data at the individual level but aggregate to the team level in order to conduct analyses and draw conclusions. When this aggregation process is properly guided by a model of higher-level composition (Chan, 1998) or emergence (Kozlowski & Klein, 2000), we can have high confidence in the construct validity and meaningfulness of the higher-level construct that results from the process. When done improperly, that is, with no validation of the underlying model for data aggregation, the result is misspecified constructs, faulty analyses, and flawed generalizations.

A very common example of this flawed procedure (names have been omitted to protect the guilty!) is to collect perceptions from individuals about team characteristics and then to blindly average the individual responses to create team-level representations. It is not the use of averages per se that is problematic. As long as conclusions regarding such aggregated characteristics are explicit about the fact that they are “averages of individual perceptions,” there is no problem. However, researchers frequently treat averaged *variables* created by blind aggregation procedures as team-level *constructs*, imbued with parallel meaning drawn from their individual-level origins. This is a major flaw. Treating an average of individual perceptions as a team-level construct necessitates a theoretically driven justification. For averaged measures, this justification is generally based on an assumption that team members have *shared* perceptions of the characteristics in question. Sharedness is evaluated prior to aggregation by showing restricted within-group variance on the characteristics, thereby establishing the construct validity of the aggregated measure. In the absence of such careful procedures, many “team-level constructs” present in the literature lack the meaning attributed to them. The example described above represents merely one model that may guide aggregation procedures. Other theoretically driven procedures are necessary for higher level constructs that conform to alternative models of emergence (Kozlowski & Chao, 2012b; Kozlowski & Klein, 2000).

Research on team phenomena must be cognizant of and consistent with the principles of multilevel theory, data, and analyses.

Time

Despite McGrath’s persistent calls for greater attention to time in team theory and research, it is perhaps the

most neglected critical issue in this area (Mohammed et al., 2009). It is, with few exceptions, poorly represented in theory and is virtually ignored in research that is largely based on cross-sectional methodologies. Temporal concerns are most prominent in the area of team development—where time is generally viewed as a simple linear progression, but it is vitally relevant to all phases of team processes and performance. Indeed, we assert that it is impossible to gain a meaningful understanding of the underpinnings of team effectiveness without an explicit consideration of time. Theorists are beginning to become more sensitive to the effects of time across a broader range of team phenomena. For example, time is an explicit factor in McGrath’s (1991) TIP model, Kelly et al. (1990) describe how temporal entrainment can pace and cycle team processes, and McGrath (1997) makes a persuasive case for the need to conceptualize team effectiveness as a dynamic and adaptive process—not a static outcome. Kozlowski and colleagues (1999) construct a model of team effectiveness that explicitly addresses developmental progression (i.e., linear time) and dynamic variation (i.e., cyclical entrainment) in the intensity of team tasks. The model considers implications for the emergence of team processes and development of flexible, adaptive teams. Similarly, Marks et al. (2001) develop a temporally based theory of team processes. In their model, team performance emerges from episodic processes comprising transition-action sequences that unfold over time. DeShon et al. (2004) examine team regulation over time. And, Chen et al. (2009) show how team processes shape team member behavior over time. We believe that these and other models are beginning to provide a sophisticated and expanded conceptualization of temporal impacts on team function and process and on the *emergence* of team phenomena (Kozlowski & Chao, 2012b). Such models provide guidance and points of departure for further efforts.

Why is time so neglected in research? We do not have a definitive answer to this question, but suspect that pragmatic challenges have worked to relegate time to low priority when researchers make the inevitable trade-offs in data collection design. The challenge for addressing time in laboratory research is that the time frame is limited in duration. It is a commonly held belief that meaningful developmental processes or emergent phenomena cannot occur and be detected in the short duration of the typical laboratory experiment. So, why bother? We think such beliefs are misguided. Many important team phenomena such as the initial establishment of norms (Bettenhausen & Murnighan, 1985), the effects of leaders (Marks et al., 2001), and the influence of regulatory focus (DeShon

et al., 2001) can develop very quickly and exert persistent effects over time (Kelly et al., 1990). A focus on carefully targeted team phenomena—those that are expected theoretically to get established early and unfold quickly—can help the field to begin mapping the implications of temporal processes on team development and functioning. Similarly, the challenge for addressing time in field research is the necessity to extend data sampling over time, with consequent effects on sample attrition. Getting access to good field samples is always difficult; getting access over time compounds the challenge. Although cross-sectional designs are clearly more efficient, they by necessity can only treat temporally relevant phenomena like “team processes” as a box—a static representation of the essence by which teams create collective products. Longitudinal designs, though less efficient, will be far more revealing of the team phenomenon under investigation. Finally, addressing time in research (i.e., determining sampling strategies) on team development and effectiveness necessitates much more attention to time frames in theory. The challenge, however, is that theory cannot incorporate precise time frames without some benchmarks for calibration. How long does it take for a team to develop? How long does it take for an experienced team to adapt to a new member or a new leader? The simple answer is that we do not know because the research literature cannot inform us and, importantly, it is *not* primarily a theoretical issue. Rather, it is a descriptive issue. The field needs good, solid, basic descriptive research on important temporal phenomena so that we can begin to establish temporal benchmarks that can inform theory and research.

Team theory and research should explicitly address the implications of time for team phenomena.

Good, solid, basic descriptive research on important team temporal phenomena is encouraged.

Research Recommendations

As we covered substantive topics in this chapter, we identified a large number of issues in need of specific research attention to resolve conceptual and/or application ambiguities. We have no intention to summarize each of those recommendations. Rather, in this last section, we highlight what we consider to be the more important issues that should shape future research on work teams in organizations.

The Nature of Teams

Organizational teams come in a wide range of varieties, with new forms being developed all the time. Such

diversity illustrates the vibrancy of the team as a primary form of work organization, but it also creates challenges. Diversity in the nature of teams has made it difficult to develop useful general models and interventions applicable to all teams. Thus, it is vital that researchers identify the boundary conditions and critical contingencies that influence team functioning and processes for different types of teams. To accomplish this, we believe that researchers need to focus less attention on descriptive classification and more attention to the underlying dimensions and characteristics that are responsible for distinguishing different types of teams (see Figure 17.2). There is relatively little theoretical value in efforts to create a team typology that does not also surface the factors responsible for differential classification (Bell & Kozlowski, 2002). Moreover, identifying the underlying characteristics that distinguish different types of teams will help make more salient the contingencies that determine effectiveness across team types. This will enable both theoretical advances as well as better targeted interventions for enhancing team effectiveness.

Composition

Historically, research on team composition has tended to focus on manifest or descriptive characteristics—size and demographics. More recently, team researchers have started to examine team composition in terms of latent constructs—ability and personality. There is also an emerging and vibrant stream of research on team fault-lines (e.g., Thatcher & Patel, in press) and other conceptualizations that consider composition configurations (Chao & Moon, 2005). These lines of research have been largely independent. We believe that there is potential value from an integration of these areas. Demographic composition has demonstrated effects, but it is difficult to imagine that such effects occur without mediation by psychological characteristics. Integrating these areas may help researchers better focus on identifying mediating characteristics relevant to both types of composition factors. Relatedly, composition research would benefit from more attention to contextual moderators that affect the composition-outcome linkage. In addition, the levels of analysis perspective can be profitably applied to this area of work. Indeed, it must be more prominently applied because a significant portion of team composition research neglects many basic principles of multilevel theory.

Understanding how to compose better teams is the key to leveraging selection as a tool for enhancing team effectiveness. Conventional selection methodology, with its focus on the individual as opposed to the team level,

generally promotes a “more is better” perspective when applied to the team level: If conscientiousness promotes better individual performance, then greater collective conscientiousness must be better for team performance. However, as we discussed previously with respect to levels issues, whether this assumption is true or not is dependent on the way in which the construct emerges at the team level: What is the meaning of team conscientiousness in the context of the team task? If it is additive, more *is* better. But, if it is configural, we need to identify the pattern or configuration of characteristics that create synergy in the team collective. We think that this idea—theoretically, empirically, and practically—is an interesting, exciting, and compelling research issue.

Formation, Socialization, and Development

Existing teams experience personnel outflows and inflows, necessitating a socialization process to acculturate newcomers to the existing informal structure. In other situations, teams are formed anew, necessitating a developmental process wherein all team members simultaneously contribute to the formation of informal structure. Although these are distinctive processes and literatures, we believe that there are parallels that allow the two literatures to mutually inform. For socialization, the primary issue is that research needs to be far more attentive to the effects of the work group on the process of individual socialization (Chen, 2005). Currently, the work group is viewed as one among many factors that affect the process rather than as the primary locus of socialization. In addition, although socialization theory conceptualizes the process as bi-directional, research typically examines it as unidirectional. Research needs to better capture processes by which the newcomer assimilates to the group, as well as processes by which the group accommodates to the newcomer (Chao, 2012). We need to better understand what insiders can do to facilitate socialization, and then train them to do so.

With respect to team development—research is needed! Although a useful foundation is provided by classic stage models (e.g., Tuckman, 1965), we believe that there is a need to validate and extend newer models that have been specifically formulated for work teams. For example, Gersick’s (1988) PEM was derived from descriptive data based on just eight project teams. Although there has been some research to evaluate the PEM and compare it with other models of group development (see Chang et al., 2003), there is relatively little work of this type and it tends to be limited to small sample sizes. The PEM has not been subjected to empirical substantiation on a large set

of teams, nor on a diverse sample of team types. Although we believe that temporal entrainment is important to team development, we do not believe that it will manifest as a uniform punctuated equilibrium in all types of teams. Indeed, research indicates that the punctuated equilibrium transition can be quite variable (Chang et al., 2003), suggesting that other factors influencing temporal entrainment may be operating (Kelly et al., 1990).

This would seem to be an important concern, but it has received no real research attention. Kozlowski et al. (1999) synthesized a broad literature base for their normative model to support the content, processes, and outcomes they proposed were relevant at different phases of development. However, efforts to examine model prescriptions are still preliminary (DeShon et al., 2001; Dierdorff et al., 2011). The model was designed to provide a prescriptive foundation for creating interventions that would promote team development at all phases of the team life cycle. Thus, we assert that solid empirical research to describe, validate, compare, and extend models of work team development is needed.

Team Effectiveness, Processes, and Enhancements

The critical focus of team effectiveness research has been on team processes that link team resources to team outcomes. Thus, conceptualizing team processes and developing interventions that enhance them have been dominant themes in this area. We organized our review around cognitive, affective/motivational, and behavioral process mechanisms.

One of the biggest challenges in the cognitive domain is the necessity to clearly disentangle team learning processes and team knowledge outcomes (i.e., mental models, transactive memory; Bell et al., 2012). Research on team knowledge outcomes is maturing and we are gaining useful insights on factors that shape them and their role in team effectiveness (DeChurch & Mesmer-Magnus, 2010).

Although more work is clearly needed, this research has moved from preliminary to more mature in nature. Transactive memory has potential utility for the cognitive domain, especially since it provides a means to address the notion of “compatible but different” knowledge at the team level. However, the current form of measurement does not directly assess the structural aspect of “compatible but different” knowledge. We think that is an issue that requires attention. Finally, team learning should be regarded as a process that is in need of direct and systematic investigation; it is fundamental to team effectiveness. Key issues include the need to develop measurement

approaches to capture it dynamically (Kozlowski & Chao, 2012b) and to distinguish it from individual learning and performance.

With respect to affective/motivational process mechanisms, work on collective efficacy has demonstrated promise as a contributor to team effectiveness. Key research issues include levels of analysis concerns in measurement, articulation of the underlying processes by which collective efficacy is formed and has effects, and examination of potential contextual moderators. The latter issue is also relevant to the cohesion–performance relationship. We need to see solid empirical demonstrations that collective mood or group emotion contribute to team effectiveness; currently, much of this work is purely conceptual. Finally, we need to see levels of analysis concerns—both conceptual and methodological—addressed in research on team conflict. Team conflict has tended to be assessed via individual level perceptions that are averaged to the team level. What kind of higher level construct is conflict? Is it shared by all team members, thereby necessitating evaluation of restricted within-team variance? Is it a configuration of team member perceptions? If so, an average misspecifies the construct. We think this work is promising but must better attend to basic levels of analysis principles.

As for behavioral mechanisms, there has been substantial progress since our prior review. Theoretical work by Marks et al. (2001) has provided a useful framework and a typology for conceptualizing team behavioral processes and their relevance to team transition, action, and reflection. Meta-analytic confirmatory factor analysis has substantiated the framework and, conceptually, the temporal linkages (LePine et al., 2008). Thus, this work provides researchers with a validated conceptual and measurement structure for assessing team behavioral processes (Fernandez, Kozlowski, et al., 2008).

Finally, we regard communication as an enabler of coordination, cooperation, and collaboration processes. Unfortunately, there is relatively little attention paid to communication in organizational psychology and behavior team research. In large measure, we think this is due to the challenges of capturing, clustering, and coding verbal communications. Perhaps if organizational researchers were more aware of automated speech capture and processing techniques used in computational linguistics, we would see more needed research on team communication behavior.

Many types of interventions have the potential to enhance team processes, but team training is chief among them. There are three overarching issues in regard to

team training research: content (what), timing (when), and techniques (how). The key research issue for training content is the extent to which the frameworks for teamwork competencies generalize from action teams to other less complex team types. For timing, the primary concern is sorting out when it is most appropriate to deliver important teamwork skills. This necessitates increased integration between the areas of training and team development. Advanced computer technologies and enhanced connectivity are creating a host of new training tools—web-based training, distance learning, distributed interactive simulation. Currently, these tools are primarily used as media to deliver content. The key research issue is how to best utilize these tools for good instructional effect. In addition, team training always raises the issue of the target for delivery: individuals or intact teams? Emerging theory has developed principles to guide this decision, but basic research is needed to establish the impact of delivery level on team effectiveness.

Leadership and Motivation

Leadership and motivation are distinct literatures, but conceptually related areas, with many leadership models focused on motivating or influencing member behavior. Both literatures are huge, and yet in general both literatures have relatively little to say about leading and motivating teams. On the leadership side, the dominant presumption has tended to be that leadership effects “average out” across group members (e.g., transformational leadership). This tends to result in theories that treat the group as an undifferentiated whole, in theories that focus on individual influence that aggregates to the group level, or in approaches that focus on leader–subordinate dyads (e.g., leader–member exchange, LMX). On the motivation side, theories in psychology are almost universally targeted at the individual level. What are the meaning and mechanisms of team-level motivation?

Both areas would benefit from theory development and research that are explicitly targeted at the team level. Since our prior review, substantial progress has emerged in both areas. First, there is much more research devoted to situating generic theories like transformational leadership and LMX in team contexts (Day, 2012). This allows us to extract value from the application and refinement of existing theory. Second, there has been more development and refinement in team-centric leadership theories, particularly those focused on leadership functions in teams. We think this is a profitable line of inquiry and should be encouraged further.

For motivation, we see the underpinnings of true team-level theory that was not apparent previously. Indeed, in our prior review we encouraged research into the development of multilevel motivation theory. Important exemplars of such research have emerged. There is research that indicates goals and feedback mechanisms operate as homologues (DeShon et al., 2004) and cross-level (Chen et al., 2009) models across the team and individual levels, demonstrating that self-regulatory motivation theories can account for the dynamic interplay of individual and team motivational processes and performance outcomes. There is even meta-analytic evidence that provides support for the practical application of goal-feedback-based approaches to the workplace (Pritchard et al., 2008). This line of inquiry is very promising and should be encouraged. Future research is advised to focus on the micro-dynamics of multilevel regulatory processes.

Continuance and Decline

As teams continue to increasingly form the basic building blocks of organizations, concerns will naturally emerge as to how to maintain their effectiveness over time. Remarkably, we know relatively little about the prospects of long-term effectiveness and the factors that may enhance or inhibit team longevity. Research on technological innovation in the 1970s suggested that mature teams become more insular, communicate less, and are less innovative than less mature teams. However, though suggestive, empirical support is quite limited. We need basic research to examine the effects of group longevity on team processes and effectiveness over the long term.

Conclusion

Teams are alive and well and living in organizations. This reality is pushing the field of organizational psychology to shift from a science and practice that is primarily focused on the individual level—our traditional roots—to a field that encompasses multiple levels: individual, team, and organization. Because teams occupy the intersection of the multilevel perspective, they bridge the gap between the individual and the organizational system as a whole. They are a juncture of the person and the system. They are a focal point. They challenge us to attend to the organizational context, task workflow, levels, and time. They challenge us to develop new theories, new methodologies, new measurement tools, and new applications, not to just attempt to dust off and generalize our current ones. This creates major challenges for many of our field's traditional methods (e.g., selection, appraisal, training), but it

also creates opportunities for theoretical innovation and advances in practice. Our field has much to learn and much to do, but we are confident that organizational psychology is capable of meeting the challenge afforded by the organization of workaround teams.

CHAPTER 18

Customer Service Behavior

ANN MARIE RYAN AND ROBERT E. PLOYHART

SERVICE ATTRIBUTES 471
EMOTIONAL LABOR AND CSB 480
TRAINING AND SOCIALIZATION OF CSB 482

DESIGN OF CUSTOMER SERVICE JOBS 485
FUTURE RESEARCH DIRECTIONS 486
REFERENCES 487

Desatnick (1994) suggested that the 21st century is either going to be the era of customer sovereignty or the era of customer rebellion and revolt. One decade into the 21st century shows evidence for both. Customers have become more empowered and a more central part of organizational planning and strategy, yet the delivery of such strategy is often far from optimal. Indeed, the ability of firms to use superior service as a means to develop a competitive advantage ultimately rests with the behavior of the service provider. In this chapter, we examine influences on customer service behavior (hereafter referred to as CSB) and how traditional industrial–organizational (I-O) psychology topics (i.e., selection, motivation) might be approached if the goal is enhancing CSB. Not all service situations are similar (i.e., the service provided in a doctor–patient relationship is not the same as at a fast-food restaurant), and therefore a discussion of CSB requires a contingency perspective.

CSB is broadly defined as any set of employee activities specifically directed toward affecting service quality (e.g., greeting or assisting customers, rectifying service failures). Note that there are many factors that influence a customer’s experience of service and the ability of employees to deliver that service (e.g., amount of computer downtime, product quality, store physical layout, unrealistic customer expectations such as on-time flight departures in bad weather) (e.g., K. A. Brown & Mitchell, 1993; J. L. Spencer, 1991). Also note that the quality of customer service depends upon what the customer desires, not just the level of service delivered (George & Jones, 1991). Our focus is on the behaviors employees engage in for the specific purpose of enhancing customer perceptions of service quality. Many different positions in the

organization may require some engagement in CSB; such behaviors will be a major role requirement for frontline service providers such as retail clerks, home repair workers, customer service call center employees, and the like (Ellinger, Elmadag, & Ellinger, 2007).

Why focus on CSB in a *Handbook of Psychology*, given the variety of behaviors individuals exhibit at work? First, service is projected to continue to be a source of growth in jobs in the United States and globally (Statistical Abstracts of the United States, 2011) and in 2005 services accounted for 76% of the U.S. gross national product and 69% globally (Earthtrends, 2011). Second, a focus on the customer has become a major component of organizational strategies, regardless of what sector the organization is in. Poor service has been found to be a key reason for switching to competitors (Weitzel, Schwarzkopf, & Peach, 1989; Zemke, 1989). Third, customer service is one area where researchers have strong evidence that employee affect and attitudes influence some bottom-line outcomes of great importance to organizations (e.g., sales, repeat business). This is an area where I-O psychologists have convincingly demonstrated that concern for the employee benefits the organization’s goals.

There have been many excellent reviews of CSB-related research (e.g., Bowen & Schneider, 1988; Bowen & Waldman, 1999; Hausknecht & Langevin, 2010; Schneider & Bowen, 1992; Schneider & White, 2004), and our goal is not to summarize or replicate those reviews. Our focus in this chapter is a contingency approach to the understanding, prediction, and influence of CSB; we hold that there are aspects of the service situation that should and do affect the choices one must make regarding how to bring about positive

CSB (Bowen & Waldman, 1999; Jackson & Schuler, 1992; Mayer, Ehrhart, & Schneider, 2009). Contingency approaches to choosing human resource (HR) practices have been discussed in the strategic human resource management (HRM) literature (Delery & Doty, 1996; Lepak, Liao, Chung, & Harden, 2006), and our chapter follows from that line of thinking. That is, HR practices are put in place to operationalize and implement a firm's strategy, and thus the firm's strategic emphasis on service will influence the manner in which the organization supports and rewards CSB.

We first describe attributes of services that may influence how one promotes CSB. This section lays the groundwork for the contingency perspective. We then review the major research and practice areas and discuss their relation to the promotion of positive CSBs in the context of a contingency model. That is, after discussing what is known about CSB and each intervention focus, we provide a table to illustrate how a contingency perspective might drive future research. An earlier edition of this *Handbook* contained similar tables; we note, unfortunately, that many of the same questions remain unanswered a decade later. Yet this neglect also provides opportunities for I-O psychologists to influence practice, as many organizations try to differentiate themselves based on their customer service.

SERVICE ATTRIBUTES

Traditional descriptions of how services are distinguished from goods refer to "IHIP characteristics" (see Moeller, 2010, for a review): the *intangibility* of services as contrasted with the tangibility of goods, *heterogeneity* or lack of standardization (often considering the fact that many services involve coproduction, or active customer participation in the production of the service, e.g., providing information regarding medical symptoms or desired hairstyle), the *inseparability* or simultaneity of production and consumption of services as compared to separation of the production and consumption of goods, and *perishability* or the fact that services cannot be stored. Schneider and colleagues (Bowen & Schneider, 1988; Schneider, 1990; Schneider & Bowen, 1985, 1992) have talked extensively about the implications of these distinctions for service management as compared to traditional manufacturing approaches; we will not reiterate all the insights provided by these writings. More relevant to this chapter is that these are attributes on which services can vary as well (e.g., some services are more tangible than

others (haircut vs. financial advice); customers may be more of a coproducer in some cases (Internet retailing vs. bricks and mortar). Variations on these dimensions can influence CSB and the interventions organizations undertake to promote CSB.

Using the first *I*, intangibility, as an example, Bowen and Schneider (1985) have noted that as intangibility increases, customers rely more on the service provider's behavior as an indicator of the quality of the service they are receiving. Yet, intangibility makes it difficult to set specific goals or prescribe specific behaviors for employees to demonstrate, leaving the organization with less control over employee behavior with more intangible services.

As another example, heterogeneity, or the extent to which the roles and expectations associated with a service interaction are "standard" or common versus *customized* (Bitner, Booms, & Mohr, 1994; Rogelberg, Barnes-Farrell, & Creamer, 1999), can vary across services. For example, Bitner et al. (1994) indicated that certain types of interactions (being seated in a restaurant) are repeated frequently so that there are standard scripts that employees and customers will know to follow. They note that when there is more unfamiliarity with what should occur or when there is interference with the standard script, there may be greater differences in employee and customer expectations. Also, Kelley, Donnelly, and Skinner (1990) noted that customization requires greater coproduction, as the customer must convey what he/she wants. In some cases, latitude in determining the extent of customization may be provided to the customer contact employee (Lovelock, 1983); for example, some customer service employees are essentially order takers, others create the service experience within their own determination (professor teaching), and others have tremendous control (surgeon, hairdresser; Lovelock, 1983). Differences in the standardization of service will influence how to best promote CSB.

Another example of how services vary is that the extent of coproduction may change the roles and behaviors of the employee (Bowen & Schneider, 1988; Legnick-Hall, 1996). Kelley et al. (1990) noted that customers have expectations regarding what the service employee should do and how he/she should behave (i.e., CSB) and what the customer should do and how he/she should behave. A mismatch between customer and service provider expectations is likely to be problematic. For example, customers who do not understand what is expected of them (e.g., clearing own table, procedures for dropping off rental cars) require more from service employees, as do those

customers who do not provide what is required (e.g., not reporting all symptoms to a doctor) or act inappropriately (e.g., angry and abusive airline passenger in a snowstorm delay; Kelley et al., 1990). Tax, Colgate, and Bowen (2006) suggested customers cause one-third of all service problems. Legnick-Hall (1996) noted that in addition to the importance of clarity of expectations, customer abilities and motivation to engage in coproduction are important influences on the outcome of the service encounter, and thereby may be important influences on an employee's CSB.

Related to the heterogeneity of services is the extent to which a specific CSB to be exhibited is inherently discretionary. Many authors have described CSB as a form of prosocial (i.e., helping) behavior directed toward customers (George, 1991; George & Bettenhausen, 1990). Debate exists, however, as to whether one should consider these role-prescribed prosocial behaviors (George, 1991) or outside formal role requirements (Morrison, 1997). Bettencourt and Brown (1997) distinguished *extrarole* CSBs (e.g., going "beyond the call") from *role-prescribed* CSBs (e.g., greet and say thank you). Bettencourt, Gwinner, and Meuter (2001) further described service-oriented citizenship behaviors as taking three forms: loyalty behaviors, as employees act as representatives of firms; participation, as service employees provide information back to the organization regarding customer needs; and service delivery behaviors, conscientiously performing the activities surrounding delivering service. In any particular organization, these forms of citizenship behaviors may be considered more or less as role requirements. Whether a CSB is role-prescribed or extrarole results in different implications for interventions to promote CSBs. For example, Morrison (1997) noted that with discretionary behaviors, organizations must create an environment where employees *desire* to engage in the CSB.

While perishability, the *P* in IHIP, may be a distinction of the service, the *type of relationship* with customers that the employee has may vary in the extent to which it lasts as well. Gutek and colleagues (Gutek, 1995; Gutek, Bhappu, Liao-Troth, & Cherry, 1999) have distinguished service relationships from service encounters. The former refers to cases where a customer and employee expect to have repeated contact in the future (e.g., hairdresser, physician). Encounters are single interactions between a customer and service provider with no expectation of future interaction, such as fast-food cashier. They also describe pseudo-relationships where customers have repeated contact with the same organizational location or unit (e.g., bank branch) but with different customer

service providers. For purposes of simplicity, we will not consider this variant. How might this distinction change how we promote CSB? Gutek et al. (1999) noted that because of expected future interaction, providing good service is in one's self-interest in relationships, whereas individuals in encounters would not have the same motivations. Monitoring employees may be more essential to the promotion of high-quality service in encounters than in relationships (Gutek et al., 1999). Researchers (e.g., Bitner et al., 1994; Rafaeli, 1993) have also noted that employees look to customers for cues on how to behave (e.g., what type of transaction is desired, satisfaction, etc.). Thus, the nature of the relationship with the customer likely influences how employees decide to behave.

One other dimension noted by several researchers as influencing how to promote CSB is the *nature of the customer contact*. For example, is the service delivered face-to-face, or by telephone, e-mail, mail, or other means (Bowen, 1986; Rogelberg et al., 1999)? Bowen (1986) noted that customer physical presence is desirable when service production and delivery are absolutely inseparable (dentistry), there are marketing advantages (add-on sales are possible), and when it allows the customer to be more involved in the production of the service (customer will perform more service tasks). The physical presence of the customer is potentially an important situational determinant of CSB. The level or amount of customer contact that an individual has (constant vs. sporadic) is also a concern. For example, Brown and Mitchell (1993) noted that tellers, who have high amounts of customer contact, felt their performance was more hindered by social obstacles (coworker behaviors, workplace disruptions) than did account representatives, who spent less time in contact with customers.

Note that these dimensions likely covary (e.g., intangibility may be related to coproduction). Also, there are other typologies of services and other distinctions among service situations that may influence CSBs and the systems developed to support those behaviors, for example, duration of contact episode (P. Mills & Margulies, 1980), supply and demand for the service (Lovelock, 1983), and internal versus external customer (George, 1990; see also Albrecht & Zemke, 1985; Zeithaml, Berry, & Parasuraman, 1993).

Further, a strategic approach to human resources (e.g., Lepak et al., 2006; Schuler & Jackson, 1987) would involve fitting HR practices to business strategy (i.e., chosen market segments such as high-end customers, aspects of service promoted such as speed or affordability, etc.).

Although we cannot consider all these possibilities here, the dimensions noted will illustrate the usefulness of a contingency approach to the promotion of CSB. In each section that follows on various I-O topics, we end with a presentation of research questions based on a consideration of these attributes.

The Conceptualization and Measurement of Customer Service Performance

Defining and measuring customer service performance is perhaps more difficult than for other types of employee performance. Part of the difficulty arises from the fact that the nature of customer service (i.e., IHIP) makes it difficult to use objective measures (e.g., Bowen & Schneider, 1988); another part of the difficulty arises because service quality ultimately lies in the eyes of the customer (Oliver, 1981; Parasuraman, Zeithaml, & Berry, 1985). A third difficulty is that what is viewed as good CSB likely varies greatly depending upon situational factors (e.g., busyness, professional level of CSB provider [doctor vs. waiter]). Thus, the provision of high-quality service is very much a dynamic, interactive, and largely subjective experience (Boulding, Kalra, Staelin, & Zeithaml, 1993).

Further complicating the conceptualization and measurement of customer service is the diffuse ways in which it has been examined in the research literature. Some studies have focused on customer perceptions of service quality, whereas others have examined supervisory ratings of employee service behaviors; some research discusses service satisfaction whereas other research discusses service quality; certain researchers focus on the emotional aspects of service and others focus on the more technical features; some research focuses on the employee and other focuses on the customer. In this section, we review the major ways that service performance has been conceptualized and operationalized at the individual level.

Conceptualization

Customer service performance is not conceptualized the same way in the I-O and service management literatures. In the I-O literature, employee service performance is generally defined as involving the types of behaviors that an employee engages in to satisfy a customer's expectations. For example, J. Hogan, Hogan, and Busch (1984) note that customer service requires three behaviors: (a) treating customers with tact, courtesy, and consideration; (b) perceiving customer needs; and (c) providing accurate and pleasant communication. A meta-analysis conducted by

Frei and McDaniel (1998), building from the development of PDI's Servicefirst Inventory (Fogli & Whitney, 1991), considered customer service to be composed of four dimensions: (a) active customer relations, (b) polite customer relations, (c) helpful customer relations, and (d) personalized customer relations. They further suggest that CSB is composed of friendliness, reliability, responsiveness, and courteousness. Thus, the I-O literature tends to conceptualize service performance as an employee performing specific behaviors in particular ways to increase customer perceptions of service. That is, the conceptualization of service performance is what is done (or should be done) on the job, as defined by a job analysis.

However, in the service management literature, the focus is on customer service performance from the customer's perspective. The two most common definitions of customer service performance are those reflecting satisfaction and quality, and the extant literature has tended to treat these as separate concepts. According to Parasuraman et al. (1985), "Perceived service quality is a global judgment, or attitude, relating to the superiority of the service, whereas satisfaction is related to a specific transaction" (p. 16). This definition is consistent with others in the marketing literature (e.g., Hunt, 1979; Oliver, 1981). In these definitions, satisfaction or quality is usually defined according to the customer's perceptions. Thus, at least in the marketing literature, it is the customer's perceptions of satisfaction with specific service transactions that, over time, accumulate into perceptions of service quality (Oliver, 1981; Parasuraman et al., 1985).

In this literature, service quality lies in the judgment of the customer regarding how well the service *received* met the service *expected* (e.g., Gronroos, 1982; R. C. Lewis & Booms, 1983; Parasuraman, Berry, & Zeithaml, 1991b; R. A. Smith & Houston, 1982). Although the conceptualization of service quality as a customer's comparison between expectations and perceived service is relatively simple, the actual description of this psychological process is not. This is because multiple forms of expectancies may exist, each type of expectancy may be multiply determined, and each type of expectancy has different implications for deriving quality perceptions (e.g., Cadotte, Woodruff, & Jenkins, 1987). Oliver (1981) discussed several theories, such as adaptation-level theory and opponent-process theory, which can be used to account for how expectancies regarding service are formed and change.

Parasuraman et al. (1991b) and Zeithaml et al. (1993) argued that customer expectations have multiple, changing levels (see also Parasuraman, Zeithaml, & Berry, 1994b).

The desired level reflects what customers expect should happen, and the adequate level reflects what they find minimally acceptable. For example, when visiting a fast-food restaurant, we might expect the service to be fast (desired level), but recognize that the lunch hour rush will require an acceptable 10-minute wait (adequate level). Thus, the desired level is to some degree higher than the adequate level. The area between these two levels is known as the “zone of tolerance,” and it is within this zone that service quality should be perceived as moderate or better. Parasuraman et al. (1991b) further note that the boundaries of the zone of tolerance (i.e., desired and adequate levels) are variable over time and situations. They also argued that the zones differ for different dimensions of service (we’ll discuss these dimensions shortly). Finally, they suggested that several factors influence how these levels might change. Specifically, the adequate and desired levels may increase when the customer has experience with the service, when there are several perceived alternatives, when the service is required in an emergency situation, when personal or situational factors make the service particularly important, and when there is a service failure (see Zeithaml et al., 1993).

Boulding et al. (1993) have provided perhaps the most complete model of expectancy formation, suggesting there are two completely different types of expectancies. “Will” expectancies reflect what a customer thinks will most likely happen in the service. “Should” expectancies reflect what a customer ideally wants to happen. Notice that this is similar to the adequate and desired levels of expectancies in Parasuraman et al. (1991b), except that Boulding et al. (1993) state that these are two different types of expectancies and not simply different levels for the same expectancy. Will and should expectancies are determined by two factors: the current service delivery and expectancies formed as a result of previous interactions. What is innovative about this model is that it attempts to capture and explain the dynamic, ever-changing *process* of forming perceptions of service quality. While Boulding et al. provided data to support the model, in practice it is somewhat difficult to measure all of the necessary constructs.

Although limited research has examined how service quality perceptions are formed, considerable research has examined the structure and content of service quality perceptions. Nearly all research in this area has used variations of the SERVQUAL dimensions identified by Parasuraman et al. (1985; see also Parasuraman, Zeithaml, & Berry, 1988; Parasuraman, Berry, & Zeithaml, 1991a). The first dimension, *tangibles*, refers to the physical

appearance of the store and service personnel. *Responsiveness* reflects the service provider’s attentiveness and readiness to provide prompt service for a customer. *Assurance* is whether the service provider is competent and is capable of using this competence to instill confidence and trust in the customer. *Empathy* is how well the service employee can understand the customer’s needs and expectations, and provide customized, individualized attention in a caring way. *Reliability* reflects whether the service provider can provide the service correctly the first time, as promised, or quickly fix problems that may arise. Of these five dimensions, research suggests that the reliability dimension is the most important across most service jobs (e.g., Parasuraman et al., 1988; Parasuraman et al., 1991a). Parasuraman et al. (1988) and Parasuraman et al. (1991a) suggest that these dimensions form the basic structure of quality perceptions, but more dimensions may need to be added depending on the service context of a particular study (e.g., Carman, 1990). Nonetheless, the dimensions identified by Parasuraman et al. (1985) appear to be endorsed by most individuals who conduct research on customer service (e.g., George & Jones, 1991; B. R. Lewis & Mitchell, 1990; Parasuraman et al., 1988; Schneider & Bowen, 1995). It is also important to recognize that research efforts conducted independent of the Parasuraman et al. (1985) framework and based on job analyses have identified similar dimensions (J. Hogan et al., 1984). Thus, as a basic structure describing the common elements of service quality, the Parasuraman et al. (1991a) dimensions appear to be reasonably well supported.

A key distinction between the I-O and service management literatures becomes apparent when we consider Boulding et al.’s (1993) model of how perceptions are formed and the SERVQUAL dimensions. Customer perceptions are based on the behavior and appearance of the service provider, the quality and price of the product (if present), and possibly even the layout of the store (Dodds & Monroe, 1985; Garvin, 1987; Zeithaml, 1987). Thus, customer service performance is only partly determined by behavior in the marketing conceptualization, while behavior is the focus of the I-O conceptualization. Obviously, these different foci indicate that multiple criteria can be considered as indicators of customer service performance—assessments of CSB (ratings by supervisors or by customers) and global evaluations of service quality (which are based on but not necessarily commensurate with behaviors; e.g., service quality can be low because of the huge demand for services, not the specific behaviors of the customer service provider). Four of the

five SERVQUAL dimensions focus on behavior, but the Boulding et al. (1993) model as well as other work suggests the performance evaluations on these dimensions are reflective of things other than just whether the customer service provider demonstrates specific behaviors (e.g., expectations based on past experiences, the environment, product features).

The service context may affect the conceptualization of performance. Using a classification system described by Lovelock (1983), Kelley et al. (1990) note that service quality may differ when the service is directed toward people, intangible or tangible things, or requires a high degree of customization. Gutek et al. (1999) described how customers may expect different behaviors from customer service providers in relationships versus in encounters, and thus the effectiveness of a single behavior may be positive or negative depending on the service context. At the end of this section on performance, we will speculate on other ways that context might influence conceptualizations of performance.

Measurement

A great deal of research has used some variation of the SERVQUAL measure (B. R. Lewis & Mitchell, 1990; Parasuraman et al., 1988). The SERVQUAL instrument contains paired expectancy items and perception items that are completed by customers. For example, an expectancy item is, "These firms should be dependable," and its corresponding perception item is, "XYZ is dependable," where XYZ refers to the specific organization. Scoring SERVQUAL involves computation of a difference score, such that each expectancy is subtracted from its corresponding perception rating to create the quality score for a specific service dimension. Quality scores (i.e., difference scores) are then summed within service dimension to create the dimension score (e.g., tangibles, reliability, etc.).

There have been numerous critiques of SERVQUAL, including: the instrument will often need to be customized to a particular setting and administered separately for each service function (Carman, 1990); the hypothesized factor structure is not supported (Babakus & Boller, 1992; Finn & Lamb, 1991); the perception-only portion of the SERVQUAL is more predictive than the service quality measure (i.e., perception–expectancy; Babakus & Boller, 1992; Cronin & Taylor, 1992; Parasuraman et al., 1991a); the use of a difference score in the original SERVQUAL conceptualization is problematic (Babakus & Boller, 1992; T. J. Brown, Churchill, & Peter, 1993); the test–retest reliability is questionable (Lam &

Woo, 1997), and other concerns (Buttle, 1996, and A. M. Smith, 1995, provide reviews).

In response to these critiques and to further refine the instrument, Parasuraman et al. (1991a) recommended assigning importance weights to each of the scales; Parasuraman, Zeithaml, and Berry (1994a) recommended measuring desired expectancy, adequate expectancy, and perceived service; and Parasuraman et al. (1994a) argued that the reliabilities of the SERVQUAL dimensions usually meet minimum standards for internal consistency and that the difference scores have practical diagnostic value. The dimensionality of SERVQUAL continues to be an area of debate (e.g., Carman, 1990; Parasuraman et al., 1994b), but unless researchers administer the quality measure to customers from within the same industry, it may not be surprising that factor structures differ. Couple this fact with the rather small sample sizes used in most of these studies, along with the analysis of difference scores, and many of the factor interpretation problems are understandable. To date, these issues have not been adequately addressed.

More general questions regarding customer service performance remain. There is a need to develop a consensus regarding the definition of the criterion space in terms of both content and sources of information. Within the I-O psychology literature, relatively few studies (e.g., Weekley & Jones, 1997) have used customers as part of the criterion development process. Instead, customer service performance is often measured via supervisory ratings of employee behaviors on dimensions identified through a job analysis (J. Hogan et al., 1984), based on the SERVQUAL measure, or merely an overall "customer service performance" dimension. A comparison of popular models of performance [e.g., Campbell's (1990) model] to the dimensions of SERVQUAL and other approaches to assessing customer service performance is needed so that a clearer conceptualization of service performance results.

Research is needed on how the source of evaluation (customer or supervisor) affects the evaluation, as it is quite possible that the same behavior can be seen as effective by one source and ineffective by the other. For example, a server who gives patrons free drinks may foster favorable customer ratings but negative supervisory ratings when this behavior is forbidden by company policy. Further, we need to understand the extent to which evaluations by different sources are driven more or less by the actual behaviors of employees versus other factors (e.g., product quality affecting customer ratings but not supervisor ratings). Different rating sources correspond with different literatures, as supervisory ratings of

service performance behavior are used in personnel selection research, while customer satisfaction ratings are used in most other areas. And little of this research uses measures based on the SERVQUAL approach, relying more frequently on Likert-type rating scales.

As noted earlier, we believe a contingency perspective that considers the various dimensions that distinguish the nature of service is a necessary perspective to promoting CSB. To truly understand customer service performance, future researchers must consider how the service context affects the conceptualization and measurement of performance. Table 18.1 provides an indication of how

TABLE 18.1 Performance

Service Attributes	Research Questions
Intangibility	<p>Is there greater agreement between supervisor and customer perceptions for more tangible service situations? To what extent do managers and customers agree in general?</p> <p>Will CSB have more weight in performance evaluations than other aspects of the service situation for more intangible services?</p>
Heterogeneity	<p>How does the extent of coproduction influence the role of actual CSB in performance evaluations? How do supervisor evaluations in situations of high coproduction account for the customer's performance?</p> <p>How can extrarole CSBs best be included in models of customer service performance? Are extrarole CSBs weighted the same as role-prescribed CSBs in performance evaluations by customers? By supervisors?</p> <p>As the service becomes more customized, does agreement between customer and supervisory perceptions in evaluations decrease? Does agreement among customers in evaluations of performance decrease? Is employee performance more variable in custom than standard situations?</p>
Inseparability	<p>How does increased inseparability affect the extent to which performance evaluations are based on CSB versus aspects of the service itself, the organizational environment, etc.?</p>
Perishability	<p>Do different employee behaviors produce different levels of effectiveness in relationships versus encounters? For example, in a relationship situation, taking the time to get to know the customer may be critical; in an encounter, trying to get to know the customer may in fact result in worse performance because it violates the customer's expectations.</p> <p>Are dimensions weighted differently in evaluating performance in relationships versus encounters (e.g., reliability, empathy)?</p>
Nature and level of customer contact	<p>Are traditional performance appraisal procedures more amenable to service contexts that contain low customer contact? Do different dimensions of performance get more weight in evaluations in situations where the customer is physically present?</p>

consideration of the situation can influence research on this topic. The table serves to illustrate how a contingency perspective might be applied, but is not exhaustive regarding potential effects of the service situation on how performance should be conceptualized and measured.

Selection and CSB

Despite the wealth of research on service management, and the large literature on personnel selection, there is little *published* research on the selection of customer service employees (Hausknecht & Langevin, 2010; Schneider & Schechter, 1991). We consider this neglect surprising because of the sheer number of service employees that must be hired to offset the high degree of attrition found in most service occupations. In the "real world," organizations are concerned with the selection of service employees, and many consulting companies and test developers have been addressing those concerns with a variety of "service-focused" instruments (e.g., Servicefirst, Customer Service Inventory, Hogan Personality Inventory, etc.). It appears practitioners have understood the uniqueness of the CSB context, but many academics have not.

As discussed previously, the provision of customer service relies primarily on the service provider identifying and meeting the customer's expectations. Many customer service jobs are primarily interpersonal and nontechnical, requiring dealing with people with diverse backgrounds, interests, values, and goals. The service provider must therefore possess the knowledge, skill, ability, and other characteristics (KSAOs) necessary for dealing with what are often stressful, demanding, and ambiguous social situations (George & Jones, 1991). It is not surprising, then, that most attempts to select service providers have focused on KSAOs unrelated to cognitive ability (see Hausknecht & Langevin, 2010, for a similar conclusion).

Indeed, the vast majority of published research indicates that personality and dispositional constructs are required for the provision of excellent service. For example, J. Hogan et al. (1984) developed a measure of "service orientation," which is a predisposition to behave in a friendly, pleasant, and empathic manner when interacting with other people, and is comprised of items reflecting adjustment (neuroticism), sociability, and likeability. The Hogan Personality Inventory (HPI; R. Hogan & Hogan, 1992) manual reports on validation studies with their service orientation measure. For a criterion of supervisory ratings of overall job performance, most of the validities are around .30. Subsequent to the J. Hogan et al. (1984) study, there have been many

demonstrations of links between specific personality traits or personality composites and supervisor ratings of customer service performance (Day & Silverman, 1989; Hurley, 1998; Liao & Chuang, 2004; Mount, Barrick, & Stewart, 1998; Ployhart, Weekley, & Baughman, 2006; Rosse, Miller, & Barnes, 1991), as well as self-ratings of citizenship behavior (Bettencourt et al., 2001).

In a slightly different conceptualization of service orientation, Saxe and Weitz (1982) developed a measure called the selling orientation/customer orientation (SOCO). The SOCO scale was designed for use with salespersons who use a blend of marketing (meeting customer demands) and selling (creating customer demands) practices. Of interest here is that the dimensions assessed by the SOCO measures are many of the same dimensions of service orientation (e.g., empathy, sensitivity), but are placed within a sales context. Saxe and Weitz (1982) found the SOCO scale was related to sales performance ($r = 0.40$). Subsequent research has extended this conceptualization and found similar relationships with service performance behaviors (Brown, Mowen, Donovan, & Licata, 2002; Grizzle, Zablah, Brown, Mowen, & Lee; 2009).

Not all studies find relationships between personality and customer service performance, however (Rogelberg et al., 1999). Hurley (1998) reviewed 13 published studies linking personality (broadly defined) and customer service from 1971 to 1996. He found that extraversion, agreeableness, and adjustment were the primary personality correlates of overall customer service. Frei and McDaniel (1998) performed a meta-analysis of service orientation measures and found an average observed validity of 0.24; after corrections for range restriction and criterion unreliability the mean validity was 0.50. Of particular interest was the lack of correlation between the service orientation measures and cognitive ability ($r = -0.06$). However, the service orientation measures were related to agreeableness ($r = 0.43$), emotional stability ($r = 0.37$), and conscientiousness ($r = 0.42$). Relationships with openness ($r = 0.07$) and extraversion ($r = 0.07$) were near zero, contradicting Hurley's (1998) conclusion that extraversion was a useful predictor.

To summarize the research to date, service orientation/customer orientation is a strong predictor of supervisory ratings of service performance, and a lesser (and less consistent) predictor of objective indices of service performance. Service orientation is primarily composed of emotional stability, agreeableness, and conscientiousness. Cognitive ability and biodata can predict supervisor ratings of performance with a magnitude similar to

personality, but the relationships tend to be more variable (Hausknecht & Langevin, 2010). One implication of these findings is that the prediction of supervisory ratings of overall service performance is likely to be greatest when the personality composite called "customer service orientation" is used rather than individual personality traits (Hough & Schneider, 1996). Many popular customer service inventories are inherently multidimensional because items are only retained if they have meaningful relations with criteria (e.g., R. Hogan & Hogan, 1992; Paajanen, Hansen, & McLellan, 1993). However, composite measures of service orientation may enhance prediction at the cost of understanding, unless test developers map the composite service orientation measure back onto traditional personality constructs. Also, little is known about whether composite service orientation measures are better able to predict turnover in customer service positions than what is possible with other established turnover predictors (Barrick & Zimmerman, 2005).

Paper-and-pencil situational judgment tests (SJTs), which present applicants with work situations and then ask them how they would respond, have been found to be predictive of customer service performance. For example, Weekley and Jones (1999) found validities of 0.16 and 0.19 for an SJT with ratings of overall service performance. Video-based SJTs, where applicants are presented with service situations on video and then respond using a paper-and-pencil format, have shown correlations with service performance in the 0.20s (uncorrected; Weekley & Jones, 1997). More interesting is that when the scoring key was based on customers' judgments, the validity increased to 0.33. Another approach is "high-fidelity" testing, such that the physical or psychological features of the job are reproduced in the selection test. High-fidelity tests would include customer service call simulations (e.g., Mills & Schmitt, 2000) and computerized tests that simulate handling of customer inquiries and accounts (Wiechmann, 2000).

Other approaches that are lower fidelity include biodata instruments and structured interviews designed to predict customer service performance. Schneider and Schechter (1991) used paper-and-pencil tests, a structured interview, and a work simulation to predict the service performance of telephone sales and service personnel. Of these methods, they found that the interview was the strongest predictor of service performance. Thus, although the research focus has been on personality testing in selecting for CSB, there are many other selection tools that might be helpful in assessing whether one is likely to be successful at customer service.

There are several research questions related to selecting for CSB that need to be addressed. Although most researchers have focused on overall service orientation, little is known about the relative merits of this approach. For example, would specific trait measures be better predictors than an overall measure of service orientation if performance is conceptualized as multidimensional? Dudley, Orvis, Lebiecki, and Cortina (2006) provide some related evidence that this may be possible with personality, but their meta-analysis did not consider service orientation. Is effective service performance dependent on a person's predisposition for service, or can appropriate training and reward structures produce similar results? Does something equivalent to a "knowledge or skill for customer contact" exist and, if so, how is it best acquired? Bettencourt et al. (2001) demonstrated that attitudes, personality, and knowledge each contributed to the prediction of service-oriented citizenship behaviors. Such broader frameworks would aid in selection system design.

Second, it is important to recognize that most of the studies presented above have predicted overall customer service performance assessed via supervisory ratings. Although the supervisor's perspective is clearly an important one, it is a limited perspective. For example, in many service contexts, the supervisor may not observe the majority of the employee's interactions with customers (Gronroos, 1982). Similarly, customers may have very negative impressions of the employee's service even though the employee performed in an organizationally approved manner (e.g., not giving customers free refills of soda). Nearly all of the validity information presented above is specific to supervisory ratings of service performance. As noted earlier, turnover might be a criterion of particular interest in service positions, yet it is understudied.

Almost all of this research has focused on individual level selection and the prediction of individual level performance. However, in many service settings, such as retail and food service, employees work as individuals *and* as part of a team. For example, a waitress may not only have her own tables to cover, but also those of a coworker if he is falling behind. Current research has in fact found that employee service orientation KSAOs, in the aggregate, may comprise a valuable form of human capital resources that contribute to organizational performance and effectiveness (Ployhart, Van Iddekinge, & MacKenzie, 2011; Ployhart, Weekley, & Ramsey, 2009; Van Iddekinge et al., 2009). In these studies, aggregate service orientation KSAOs result in some rather sizeable improvements in financial and performance metrics.

KSAOs other than personality traits may also relate to providing good customer service and should be considered more fully in research. It is surprising that there is not more research on cognitive ability in service contexts. Researchers may perhaps believe (based on existing validity generalization evidence) that ability will be a strong predictor, but the service context may be one where ability is not much better than personality. Likewise, there is little research on knowledge in service contexts, although some research on experience (a correlate of knowledge) suggests knowledge might be important (e.g., Allworth & Hesketh, 2000). Other predictor constructs more aligned with CSB, such as emotional intelligence, may have even greater relationships. Likewise, other predictor methods, such as higher fidelity simulations and games, may better contribute to the prediction of service performance behavior.

Finally, how context factors into the personality-service relationship needs to be more closely examined. The same KSAOs would not be required for a service provider interacting with customers over the phone as would be necessary for someone working face to face with customers. Similarly, the demands and expectations of the customer may change the predictive validity of various personality constructs. For example, KSAOs relating to fostering long-term relations (e.g., empathy) may be most important in a service *relationship* because the customer expects the employee to remember his or her information and preferences. However, KSAOs such as extraversion may be most important in a service *encounter* because the customer may have only self-interest as a primary goal, with no concern for the service provider (e.g., Gutek et al., 1999). Given that service is IHIP, the criterion is one that is likely to be quite affected by context, suggesting that KSAO-service performance relationships may not be as generalizable as predictive relationships for other types of performance. Table 18.2 illustrates how a contingency approach might influence research questions in this area.

Service Climate and Employee Attitudes

In contrast to the limited research on the prediction of individual CSB, there has been active interest in understanding how service climate and aggregate employee attitudes relate to business unit-level performance and financial effectiveness. Schneider and colleagues have been the leaders in researching service climate, defined as employee perceptions of what the organization rewards and supports concerning customer service (Schneider,

TABLE 18.2 Selection

Service Attributes	Research Questions
Intangibility	Is the relationship between personality or service orientation and CSB stronger as the service becomes more intangible?
Heterogeneity	Does the personality of the service provider interact with the personality of the customer to determine the nature of coproduction? Is there a need for service providers to “fit” customers, and vice versa? Does service orientation (or more basic traits) predict extrarole behaviors and prescribed CSBs equally well? Does the provision of customized service place greater demands on the job knowledge and technical competencies of employees than the provision of standard service? That is, will cognitive ability and job knowledge have stronger relations with service performance in customized rather than standard settings?
Inseparability	How do the personalities of the customer and service provider interact? Are those who possess more of certain traits, such as agreeableness, able to work with a greater diversity of customers?
Perishability	Is there a difference in the KSAO requirements for different service encounters? For example, less “perishable” relationships require KSAOs that reflect a willingness and ability to maintain social relations and foster harmonious interactions with relatively few customers. Encounters require KSAOs that reflect a willingness and ability to deal with many customers in a short-term setting, with no real need to develop social relations.
Nature and level of customer contact	Are personality and service orientation better predictors for face-to-face service jobs rather than ones without the customer physically present? Does the amount of customer contact (i.e., continuous vs. sporadic) moderate the validities of customer orientation measures?

Gunnarson, & Niles-Jolly, 1994). Researchers have identified how a climate for service relates to more positive customer perceptions of service as well as examined what defines and creates a more positive service climate (e.g., Burke, Rupinski, Dunlap & Davison, 1996; Liao & Chuang, 2007; Salvaggio et al., 2007; Schneider, Ehrhart, Mayer, Saltz, & Niles-Jolly, 2005; Schneider, White, & Paul, 1998). In general, there is a consensus that a climate for service is a key element in motivating positive CSB by employees. There are a number of methodological and theoretical issues that have been raised by researchers in the area that help in understanding the boundaries of service climate effects (e.g., justification of data aggregation, Schneider et al., 1998; influence of unit size and location, Burke et al., 1996; Hausknecht, Trevor, & Howard,

2009; strength of climate as a moderator of the relation between climate and outcomes, Schneider, Salvaggio & Subirats, 2002; different configurations for climate, Schulte, Ostroff, Shmulyian, & Kinicki, 2009; and service attributes as boundary conditions; Mayer et al., 2009).

In addition to establishing the link between service climate and customer perceptions of service quality, there have been several other relationships that have been the focus of “linkage research.” For example, researchers have examined the link between a climate for service and a climate for employee well-being (Abramis & Thomas, 1990; Schneider et al., 1998). The suggestion has been made that a strong concern for customers by employees will not exist without a strong organizational concern for employees. As Schneider and Bowen (1992) noted, a climate for employee well-being does not presuppose a climate for service—one can have well-treated employees and not have policies that promote service excellence. Indeed, Chuang and Liao (2010) found that concern for customers and concern for employees had unique effects on market performance, but through different mediators (service performance and helping behaviors; respectively). The common cause of employee and customer concern was the presence of high-performance work systems, but other research suggests the importance of organizational support for more localized service delivery (Ehrhart, Witt, Schneider, & Perry, 2011).

A third focus has been the establishment of links between customer perceptions of service and aggregate employee attitudes (e.g., Hausknecht et al., 2009; Rucci, Kirn & Quinn, 1998; Ryan, Schmit, & Johnson, 1996; Schmit & Allscheid, 1995; Schneider & Bowen, 1985; Schneider, Parkington, & Buxton, 1980; Thompson, 1996; Tornow & Wiley, 1991; Wiley, 1991, 1996). The rationale for these links is that customers are affected by the mindset of employees (Ulrich, Halbrook, Meder, Stuchlik, & Thorpe, 1991); employees who feel negatively about the organization and the job will transmit that affect in serving customers, thereby influencing customer perceptions of the organization and the service received. Note that employee climate for service perceptions is more strongly related to customer opinions than employee well-being perceptions (Brooks, 2000).

Finally, several researchers have linked employee service climate perceptions and aggregate attitudes to organizational outcomes such as profits, sales dollars, and customer retention (Burke et al., 1996; Gupta & Zeithaml, 2006; Heskett, Jones, Loveman, Sasser, & Schlesinger, 1994; Schneider & Bowen, 1985; Schneider et al., 1980, 2005; Schneider, Macey, Lee, & Young, 2009; Schneider,

White & Paul, 1997; Thompson, 1996). Meta-analyses have found generalizable support for a reasonably strong relationship between employee attitudes and service, financial, marketing, and accounting-based business outcomes (e.g., Harter, Schmidt, & Hayes, 2002). More recent research is emphasizing the mediated relationships between service climate, employee attitudes, customer satisfaction, and business outcomes. The general finding is that customer satisfaction mediates the relationship between service climate or attitudes and business unit outcomes (Schneider et al., 2009; Schneider et al., 2005).

The causal order between service climate or aggregate attitudes and business outcomes has been the subject of considerable scrutiny (see Ryan et al., 1996). Schneider, Hanges, Smith, and Salvaggio (2003) found some types of aggregate job attitudes were caused more by business outcomes than the other way around. In contrast, a meta-analysis by Ricketta (2008) found slightly more support for a model where aggregate attitudes influence performance. It is difficult to determine the causal direction when studying existing organizational systems (as they are path dependent), but there is no doubt that the relationship between aggregate employee attitudes and business unit performance are related dynamically and reciprocally. The potential time lags that exist between service climate, attitudes, and outcomes remain a relatively unexplored issue. It is difficult to determine how long it takes for organizational service climate to affect customers or for customers to affect the organization's climate, and it is also unknown how long effects might persist (although see Schneider et al., 2003; Schneider et al., 2009, for some evidence about temporal lags).

Thus, a climate for service as well as general positive employee attitudes appear to influence customer satisfaction, presumably partly through influencing CSB (e.g., Grizzle et al., 2009; Liao & Chuang, 2004). Recommendations for improving service include promoting a service climate (see Ahmed & Parasuraman, 1994; Schneider, Chung, & Yusko, 1993; Schneider et al., 1994, for discussions of issues in developing a service climate) and treating employees well so as to enhance their job satisfaction. A strong climate for service is created via organizational leaders and managers emphasizing and rewarding positive CSB, logistical and operational support, appropriate staffing of positions, quality training programs focused on CSB, and communication and cooperation (Ehrhart et al., 2011; Schneider & Bowen, 1992; Schneider et al., 1993, 1994, 2005). Also, employee predispositions to be satisfied (Judge, 1993) might be considered in selection for customer service positions, as selection on service-related

TABLE 18.3 Climate and Attitudes

Service Attributes	Research Questions
Intangibility	Does service intangibility moderate the influence of service climate on CSB, such that a stronger relation is observed for more intangible services? Does service intangibility moderate the relation of employee and customer perceptions of service such that a stronger relation exists for more tangible services?
Heterogeneity	Does the extent of the role of the customer in production of the service influence whether a reciprocal influence of customer attitudes on employee attitudes is observed? Does heterogeneity influence the causal direction between service provision and customer satisfaction? Is extrarole CSB exhibition more influenced by service climate than role-prescribed CSB? Do service climate and employee attitudes have a greater influence on CSB in customized than standard service situations? Does customization result in greater stress?
Inseparability	Is the link between employee attitudes and organizational outcomes stronger in more simultaneous production and consumption situations than in those that are less simultaneous?
Perishability	Does service climate play a greater role than individual differences in CSBs exhibited in encounters than in relationships? Are employee perceptions negatively related to outcomes such as profit and productivity in encounters and positively related in relationships (Brooks, 2000)?
Nature and level of customer contact	Are employee and customer perceptions of service more highly related in situations of customer physical presence and in situations of greater customer contact?

KSAOs can enhance service performance individually and collectively (Frei & McDaniel, 1998; Liao & Chuang, 2004; Ployhart et al., 2006, 2011; Van Iddekinge et al., 2009).

A contingency approach suggests differences in how one should implement findings on climate and attitudes. Table 18.3 lists some research questions. Attributes of service might moderate the relations between employee perceptions of service climate and customer perceptions of service climate (see Mayer et al., 2009), as well as between employee attitudes and customer perceptions more generally, and between employee attitudes and organizational business outcomes.

EMOTIONAL LABOR AND CSB

An important component of the customer service experience is the affect or emotions expressed toward or in the

presence of customers (George, 1990, 1995; Rafaeli & Sutton, 1987, 1989). Measures of emotional display in customer service settings examine whether a greeting or smile was provided and eye contact made with the customer. The rationale for a relation between employee affective displays and customer responses is that of emotional contagion (Hatfield, Cacioppo, & Rapson, 1994), which argues that individuals absorb the affective states of those with whom they interact. Researchers have demonstrated that employee positive affect is related to CSB and customer perceptions of service quality (Kelley & Hoffman, 1997). George (1991) demonstrated that those who experienced positive moods at work (i.e., in the past week) were more likely to engage in role-prescribed prosocial behavior or CSBs, as well as in helpful behaviors that were not role prescribed (e.g., helping coworkers; see also George, 1990). Researchers have noted that both the affect displayed by individual employees and the emotional expression of the group may be relevant to customer service (affective tone, George 1990, 1995; emotional front, Pugh, 1999; Rafaeli & Sutton, 1989). For example, group positive affective tone has been found to be positively related to customer service performance (George, 1995).

A particularly active area of CSB research in recent years relates to emotional labor. Hochschild (1979, 1983) defined *emotional labor* as expressing socially desirable emotions as a role requirement. Emotional labor involves not only acting in prescribed ways (smiling) but also suppressing emotions (anger at unreasonable customers; Ashforth & Humphrey, 1993, 1995; Grandey, 2000; Hoobler, Duffy, & Tepper, 2000). Emotions displayed in a service encounter may be genuine rather than acted; that is, the employee may be highly empathic (Ashforth & Humphrey, 1993; Rogers, Clow, & Kash, 1994; Tolich, 1993). Emotional labor research has noted a distinction between deep versus surface acting, with the former involving effort to align displayed and felt emotions and the latter involving suppression of felt emotion and display of role-required emotion (Brotheridge & Lee, 2003). Considerable research suggests engaging in surface acting leads to emotional exhaustion and other negative effects on well-being (see Hülshager & Schewe, 2011, for a meta-analytic review). Further, deep acting can enhance job performance (Hülshager, Lang, & Maier, 2010). Emotional labor also can mediate the effects of other variables (e.g., customer incivility) on CSB (Sliter, Jex, Wolford, & McInnerney, 2010).

If an organization wanted to influence CSB by affecting employee emotional regulation, what action might it take?

George (1991) notes that those with higher positive affectivity (trait) could be selected, or the physical surrounding, the nature of social interactions, and other situational characteristics might be manipulated to positively affect mood. Others have suggested that hiring highly empathic individuals may lead to greater responsiveness to customer needs (Rogers et al., 1994). However, Axtell, Parker, Holman, & Totterdell (2007) suggested that while employee ability to take a customer's perspective influences service quality, genuine feelings of empathy are not required to achieve perspective-taking. Emotional display rules can be developed and employees can be trained in their execution (Ashforth & Humphrey, 1993; Rogers et al., 1994, Tolich, 1993) and monitored and rewarded for performing them. Gosserand and Diefendorff (2005) demonstrated the importance of employee motivation to adhere to display rules in order for them to affect CSB. Also, note that culture may influence the acceptability of displaying emotions not felt and/or expressing emotions in the workplace (Bozionelos & Kiamou, 2008), making the ease of regulating employee emotional display more challenging in certain cultures.

A contingency approach is helpful for determining best ways for organizations to influence emotional displays and affective tone, as well as the negative effects of emotional regulation (see Table 18.4). For example, Hoobler et al. (2000) noted that engaging in emotional suppression as a means of regulating emotion may have negative rather than positive effects on customer perceptions in long duration or repeated interactions with the same customers; in situations that are not one-time encounters, it may be better to train employees to regulate emotion via reappraisal rather than suppression. Affect may be more important in terms of influencing CSB and customer perceptions in certain types of service contexts (e.g., more intangible services, physically present customers). The effects of emotional labor on employees may also differ by context; Johnson and Spector (2007) found that autonomy alleviated negative outcomes for those engaged in frequent emotional labor. Emotion may be easier for employees to regulate if they are in continual customer contact (i.e., get into and stay in a role), as opposed to occasional customer interactions; or it may be more difficult to regulate emotion when there is no break from customer interaction. Indeed, Bozionelos and Kiamou (2008) found that more frequent surface acting, as well as engaging in deep acting of high intensity, was especially exhausting. The effect of affect on CSB is likely also to be contingent on employee characteristics. For example, Forgas, Dunn, and Grandland (2008) demonstrated that less experienced retail sales

TABLE 18.4 Emotional Labor

Service Attributes	Research Questions
Intangibility	Does group affective tone have a greater effect on customer perceptions when the service is more intangible? Is emotional labor more frequently required, more intense, or more influential on well-being when services are more intangible?
Heterogeneity	Does the extent of customer involvement in production influence the difficulty of regulating emotions? Is role-prescribed emotional display less strongly related to customer perceptions of service quality than extrarole emotional display? Is positive affect positively related to engaging in extrarole CSBs (George, 1990, 1991)? Is emotional regulation easier in standard than in customized service situations?
Inseparability	Does employee affect have a greater influence on organizational outcomes the more simultaneous the production and consumption?
Perishability	Is surface acting more difficult in relationships than in encounters? Is there greater motivation to engage in emotional regulation in relationships than in encounters? Does emotional display have more of an impact on customer perceptions in relationships than in encounters?
Nature and level of customer contact	Is emotional regulation more difficult with physically present customers than on the phone or with electronically present customers? Is emotional regulation more difficult for those with more customer contact?

staff were more influenced in the quality of their CSB by transient mood than more experienced staff, suggesting the potential value of positive mood induction (e.g., rewarding feedback), particularly among new customer service employees. As another example, Chi, Grandey, Diamond, and Krimmel (2011) found interactive effects between extraversion and surface and deep acting on performance.

Beyond emotional labor, there are studies of employees in boundary-spanning roles such as customer service providers (Boles & Babin, 1996; Singh, Goolsby, & Rhoads, 1994; Singh, Verbeke, & Rhoads, 1996; Spencer, 1991; Weatherly & Tansik, 1993) that indicate other stress sources. Stressors of particular concern for customer service providers include role ambiguity and conflict (i.e., between demands of customers and management, or between demands of different customers; Bowen & Waldman, 1999; Hartline & Ferrell, 1996; Shamir, 1980; Weatherly & Tansik, 1993), interpersonal conflicts with customers (Bowen & Waldman, 1999; Shamir, 1980), and

unusual hours and work–family conflict (Boles & Babin, 1996). In terms of our set of service dimensions, we might expect certain types of customer service positions to provide different stressors (e.g., role ambiguity may vary with intangibility; interpersonal conflict and emotional constraint will vary with the nature and level of customer contact) and therefore require different types of support systems and different stress management interventions.

TRAINING AND SOCIALIZATION OF CSB

Training is considered critical to the success of service organizations. Desatnick (1994) noted that among sixteen top service providers, one common theme was that all devoted considerable resources to training. However, Sussman (2006) states that firms often invest less than 1% of a frontline service employee's salary in his or her development, and Butcher, Sparks, and McColl-Kennedy (2009) note that most small service firms, such as those in hospitality, do not invest in training. Schneider and Bowen (1992, 1995) describe two types of customer service training: formal and informal. *Informal* training is primarily directed toward orienting the new employee into the climate and culture of the organization through interactions with coworkers, such as socialization. *Formal* training involves designing and delivering programs and exercises where the individual is taught how to be a better service provider. Schneider and Bowen (1995) note that both types of training send employees the signal that service is important and valued, and thus contribute to fostering a service climate.

Socialization is seen as a critical way to influence CSB. Researchers have noted that newcomer success on the job is related to seeking and being provided with information on how to do the job effectively (Bauer & Green, 1998). Because service employees often have some discretion in how they perform their job duties and organizations have less control over CSBs, employees must learn what is considered appropriate behavior. However, the role ambiguity associated with many customer service positions makes this process more difficult. Kelley (1992) found that socialization affected both motivation (direction and effort) and service climate, and it is through these constructs that socialization influenced employee service orientation. Thus, socialization may not always have a direct effect on CSB, but may do so indirectly through introducing and reinforcing a service climate.

Researchers have discussed tactics organizations might use to socialize newcomers (Ashforth & Saks, 1996;

Jones, 1986; Van Maanen & Schein, 1979), typically labeling them as *institutionalized socialization*, which is collective, formal, and sequential and encourages newcomers to passively accept preset roles, and *individualized socialization*, which is individual and informal and should allow newcomers to adopt unique approaches to their roles. In terms of service situations, whether an organization chooses to employ institutionalized or individualized socialization tactics should vary with features of the service context, requiring innovative customer service providers (use individualized socialization) or consistent and standard service (use institutionalized socialization).

Morrison's (1993) work on newcomer information seeking also may indicate some important issues in socialization of those with customer service roles. For example, she found that role clarity was related to the frequency with which newcomers sought information about job requirements, role behaviors, and performance feedback. For service providers, the availability and sources of such information likely vary with aspects of the service context (e.g., standardization of the service, customers as coproducers).

Formal training programs are also seen as critical for service organizations. Schneider and Bowen (1992) note three categories of service training content: (a) technical skills (how to use the cash register); (b) interpersonal and customer relation skills (how to interact with difficult customers, or how to identify customer expectations); and (c) knowledge concerning cultural values and norms. Thus, the relative importance of these three skill categories in a given setting should be reflected in training content. Our contingency approach suggests that training needs analyses will indicate different needs depending upon the service context. For example, in studying logistic service provider firms, Ellinger et al. (2007) found high levels of formal training for highly empowered workers was actually suboptimal, as employees received inconsistent messages regarding what to do.

Factors facilitating transfer of training may also vary more in their influence in service settings than for other jobs. Yelon and Ford (1999) argued that the nature of a task makes a substantial difference in the process of transfer and presented a model of training transfer that fits well with our contingency approach. They contrasted closed skills, where the circumstances when they are used as well as how they are performed are standard (e.g., checking in an airline passenger) to open skills, where the skills have to be adapted to varying circumstances and there is no one right way to perform (e.g., rerouting

passengers from a canceled flight). They also note that skill performance can vary from heavily supervised situations to very autonomous work settings. Yelon and Ford argue that most training transfer research has focused on supervised, closed skills. Although there are cases where CSBs may be supervised and require the use of closed skills, we have noted earlier that many service settings will require CSBs that are the result of more open skills and also will be performed in unsupervised settings. Yelon and Ford propose different approaches to training transfer for these different situations. For teaching closed skills, they suggest using high-fidelity simulation training, specifying conditions for use of the skill, and providing incentives for adhering to a set procedural checklist. For autonomous open skill situations, they recommend training in how to modify procedures and suggest varying the conditions of practice. Transfer of training in service contexts may be difficult because customers are a large part of the service context. That is, employees may be trained in certain skills but individual differences in customer behavior may uniquely affect the proper application of those skills.

There are many research issues related to CSB socialization and training. Table 18.5 provides some questions based on our contingency approach. As we noted in the sections on performance and selection, we need to better understand the relative importance of technical, interpersonal, and cultural KSAOs for each of the service contexts to better understand where training should be focused. Also, relative to technical skills, effective training for interpersonal skills, emotional regulation, and so on, has not been as well researched. The best methods to teach CSB may vary by context factors (e.g., formal training with practice may be more appropriate for standardized service situations, but customized services may require more intensive and individualized training as well as greater time spent on observational learning).

Motivating CSB

Much has been written regarding the application of motivational theories and techniques in efforts to enhance CSB (e.g., behavior management techniques, Crowell, Anderson, Abel, & Sergio, 1988; Luthans & Waldersee, 1992; Rice, Austin, & Gravina, 2009; Wilson, Boni, & Hogg, 1997; self-regulation, Waldersee & Luthans, 1994; providing bonuses and recognition programs, Bowen & Waldman, 1999; Desatnick & Detzel, 1993; Oliver, 1993; Zemke & Schaaf, 1989; monitoring and control systems such as secret shoppers, customer satisfaction surveys, and

TABLE 18.5 Training

Service Attributes	Research Questions
Intangibility	As intangibility increases, does formal training become a less effective means of influencing performance? Do newcomers engage in more information seeking with intangible than with tangible service positions?
Inseparability	As simultaneity increases, does formal training become a less effective means of influencing performance?
Heterogeneity	As coproduction increases, is training on interpersonal sensitivity more important to overall performance? As coproduction increases, do the conditions that facilitate training transfer change? With greater coproduction, is the customer a greater source of socialization information? Do newcomers engage in more information seeking in situations of greater coproduction? Should organizations employ more individualized than institutionalized socialization in situations of greater coproduction? Is informal socialization more important than formal training in situations where CSB is considered extra-role? As the service becomes more customized, does formal training on technical skills become more critical to effective performance? With greater customization, is the customer a greater source of socialization information? With greater customization, should organizations employ more individualized than institutionalized socialization?
Perishability	Is different training content needed for relationship and encounter contexts? For example, negotiation training may be more important for relationship contexts while diversity training may be more important for encounter contexts. Is the customer a greater source of socialization information in relationships than in encounters?
Nature and level of customer contact	As the level of customer contact increases, do different types of interpersonal skills need to be trained? Is refresher training more important for jobs with less frequent customer contact?

electronic monitoring of calls, Shell & Allgeier, 1992; Zeithaml, Berry, & Parasuraman, 1988). Space precludes a detailed review here. Although many of these efforts have reported some positive outcomes, it is also clear that the usefulness of traditional motivational tools such as clarifying expectations, goal setting, providing feedback, and recognizing and rewarding positive behaviors has been less than expected by many customer service researchers.

Why are there difficulties in applying motivational tools to CSB? Morrison (1997) argues that traditional

approaches may prove challenging to implement because it is difficult to monitor service quality, providing extrinsic incentives for CSB can undermine intrinsic motivation, and prescribing behaviors can limit flexibility and be viewed negatively by customers. Because intangibility, inseparability, and heterogeneity result in idiosyncratic situations and unpredictable customer behavior, management cannot resort to typical means of controlling and monitoring behavior such as goal-setting or developing rules and procedures (Bowen, Siehl, & Schneider, 1989; Jackson & Schuler, 1992; Schneider, 1990). Further, Bowen and Waldman (1999) noted that because customer satisfaction is seen as linked to a group of employees rather than to one individual's performance, the focus of rewards for CSB may be more appropriately linked to the group level.

Thus, although the practitioner literature recommends that precise performance standards for CSB are essential (e.g., Desatnick, 1994) and that management should train and reinforce these standards, empirical researchers do not all agree. Recommended approaches to motivating CSB do not rely as heavily on defining expected behaviors. For example, a climate for service can be the substitute for management control systems (Bowen & Schneider, 1988; Bowen et al., 1989). Morrison (1997) recommends relying on propositions of social exchange to encourage positive CSB. Cadwallader, Jarvis, Bitner, and Ostrom (2010) demonstrated that greater motivation to participate in implementing a service innovation can be induced by increasing both empowerment and role clarity. George and Jones (1991) suggest that monitoring and reward systems should not be tied to the demonstration of specific behaviors, as good customer service will mean varying behaviors to meet what the customer desires.

Researchers have also noted specific influences on motivation and behavior that may be strong in service contexts. For those involved in service relationships rather than just service encounters, other rewards may accrue as they would from any interpersonal relationship. For example, Beatty, Mayer, Coleman, Reynolds, and Lee (1996) documented how successful sales associates felt rewarded by the affection of long-term customers and the feelings of self-worth and accomplishment from helping their customers. They note that the customer service literature does not discuss, as a reward, the friendships and social connections developed as part of a service relationship.

Also, Rafaeli (1993) has noted that customers and coworkers have a more immediate, constant, and powerful influence over CSB than do formal policies, management

control systems, or training programs. If management control of CSB is limited, to what extent can or should management attempt to influence *customer* behavior and thereby influence CSBs shown by employees? For example, clarifying for customers what are appropriate service expectations, forewarning of slowdowns, and posting signs like “no shirt, no service” or “no refunds without a receipt” can have an impact on CSB by influencing the customer’s expectations and behavior (Rafaeli, 1993).

Most of the research applying organizational justice theories to service contexts has concentrated on the customer’s feelings of being treated fairly (e.g., Blodgett, Granbois, & Walters, 1993; Blodgett, Hill, & Tax, 1997; Goodwin & Ross, 1992; A. K. Smith, Bolton, & Wagner, 1999) rather than on how employee justice perceptions influence CSB. The past several years have seen increased attention to how employee perceptions of justice affect their willingness to engage in CSBs. This research applies justice theory in several ways. First, there are studies showing that justice from the organization (fair treatment by the employer or supervisor) affects willingness to engage in extrarole CSBs (e.g., Bettencourt & Brown, 1997; Moliner, Martinez-Tur, Ramos, Peiro, & Cropanzano, 2008). Second, customer unfair treatment of employees as well as their coworkers affects the amount of emotional labor employees engage in, thereby increasing potential negative effects on well-being (e.g., Rupp & Spencer, 2006; Spencer & Rupp, 2009). Third, customer unjust treatment can lead to employee retaliatory behaviors, such as sabotage (e.g., Skarlicki, vanJaarsveld & Walker, 2008). Finally, aggregated justice perceptions of employees relate to unit-level customer satisfaction (Simons & Roberson, 2003). These findings regarding treatment by employers and customers may be affected by context. For example, unjust treatment by customers may have more of an impact on subsequent CSB in relationships than encounters, or in face-to-face contexts; unjust treatment from a supervisor may have more impact on CSB in customized than standardized settings.

Table 18.6 provides several ideas regarding how a contingency approach might suggest which motivational techniques would work best in each type of service setting. For example, the more intangible, inseparable, or heterogeneous the service, the less effective will be reward systems and other motivational techniques that rely on precisely defining expected behaviors. More research is needed on current motivational theories in service settings, such as work on the application of self-regulation research to CSB and the nature of influences on customer service self-efficacy.

TABLE 18.6 Motivation

Service Attributes	Research Questions
Intangibility	<p>Is intangibility negatively related to the ability to prescribe expectations?</p> <p>Is intangibility negatively related to the ability to monitor CSB?</p> <p>Do employees feel CSBs are less recognized and rewarded when intangible services are delivered?</p>
Inseparability	<p>Is simultaneity positively associated with self-monitoring?</p>
Heterogeneity	<p>Does greater coproduction result in less prescription of expectations and greater difficulty in monitoring service quality?</p> <p>Do employees in coproduction situations feel more negatively about the recognition and rewarding of their CSBs?</p> <p>As social exchange principles underlie the motivation of extrarole CSBs, what is the relative influence of exchange with the organization versus exchange with the customer in determining whether a positive CSB will be demonstrated?</p> <p>Are customized service situations more difficult to monitor than standardized situations in terms of service quality?</p> <p>Are techniques like goal setting more effective in standardized versus customized situations?</p> <p>Does supervisor unjust behavior have greater impact on CSB in customized than standardized settings?</p>
Perishability	<p>Does the specification of expectations have less of an influence on performance in relationships than in encounters?</p> <p>Because of self-interest, is there less need for external rewards of CSB in relationships than in encounters?</p> <p>Is the monitoring of CSB more important to ensuring good service in encounters than in relationships (Guttek et al., 1999)?</p> <p>Does customer unjust behavior have greater impact on CSB in relationships than encounters?</p>
Nature and level of customer contact	<p>Is the specification of expectations and monitoring and rewarding performance more difficult for physically present customers than for virtual customers?</p> <p>Does the effectiveness of goal setting and traditional reward and recognition programs vary with the level of customer contact on the job?</p>

DESIGN OF CUSTOMER SERVICE JOBS

Studies of how job design can facilitate CSB have primarily focused on the role of discretion or empowerment, although a few have been concerned with other job characteristics (Campion & McClelland, 1991, 1993; Rogelberg et al., 1999). Campion and McClelland (1993) found that task enlargement appeared to have costs for customer service, based on employee self-reports, but knowledge enlargement (adding understanding of procedures or rules) led to better customer service, based on employee and

manager reports. Rogelberg et al. (1999) found that job characteristics (e.g., autonomy) accounted for a significant amount of variance in CSB.

Many researchers have discussed empowerment as a means of enhancing customer service quality (Bowen & Lawler, 1992; Fulford & Enz, 1995; Kelley, 1993; Morrison, 1997; Sparks, Bradley, & Callan, 1997; Weaver, 1994; Zeithaml et al., 1988; Zemke & Schaaf, 1989). Jackson and Schuler (1992) argued that intangibility, simultaneity, and coproduction require the job be enriched so service firms practicing greater autonomy will be more effective. Axtell et al. (2007) advocate broadening employee responsibilities as a means of increasing their ability to take a customer's perspective and thereby increasing service quality. However, most researchers have also cautioned about potential negative effects of empowerment on CSB. For example, Sparks et al. (1997) showed that empowerment, in and of itself, was not a positive influence on customer evaluations, which also depended on service provider communication style. Kelley (1993) noted that it is important to understand what determines when employees will exercise the discretion they have been given. That is, Bowen and Lawler (1992) discuss the costs of empowering service employees, including the possibility of inconsistency in service delivery and recovery situations, too great or inappropriate "giveaways," and poor decisions. Moss, Salzman, and Tilly (2008) also showed that flat organizational structures led to lower quality customer service in call centers than more layered hierarchies. Finally, Hartline and Ferrell (1996) found that empowered service employees experienced greater role conflict and ambiguity.

Several authors have advocated a contingency approach to empowerment (Bowen & Lawler, 1992; Schneider & Bowen, 1992). For example, if the organizational strategy is to provide quick and reliable service, a nonempowered employee who is "going by the book" may be what the customer wants. The positive effects of empowerment on an individual's job attitudes (e.g., increased job satisfaction, Fulford & Enz, 1995; reduction in role ambiguity, Singh, 1993; but see also Hartline & Ferrell, 1996) may be accompanied by positive effects on customer satisfaction or they may be accompanied by negative outcomes in service quality, depending on aspects of the situation. However, one might speculate that empowerment might also positively affect turnover (i.e., lead to reduced turnover), and high turnover contexts are unlikely to be ones with high overall service quality.

Bowen and Lawler (1992) point directly to two of our contingency variables—encounter versus relationship

TABLE 18.7 Job Design

Service Attributes	Research Questions
Intangibility	Is empowerment more effective with more intangible than tangible services?
Heterogeneity	Is empowerment more effective the greater the level of coproduction? Are empowered employees more likely to engage in extrarole CSBs than nonempowered employees? Does empowerment have more of an effect on CSB and customer perceptions in customized than in standard situations (Bowen & Lawler, 1992)?
Inseparability	Is empowerment more effective with more simultaneous services?
Perishability	Does empowerment have more positive effects on CSB and customer perceptions in relationships than in encounters (Bowen & Lawler, 1992)?
Nature and level of customer contact	Does autonomy have more positive and more negative effects in customer-present situations? Does empowerment result in less consistent service in jobs with sporadic customer contact?

and predictability of the service situation—as important factors in deciding whether to empower workers. They advocate greater empowerment in relationship situations than when ties to the customer are only for short transactions. They also suggest that if there is unpredictability in the types of requests, empowerment is appropriate; if expectations of customers are simple and predictable, then one can use a less empowered approach and have more policies and rules. We expand the notion of a contingency approach to empowerment and job design in service settings by suggesting other propositions to explore in Table 18.7.

FUTURE RESEARCH DIRECTIONS

Throughout this chapter we have identified many research questions to be addressed and have emphasized the need to consider the service context in applying HR tools and strategies. There are a few areas we have not mentioned that are also likely to be future foci. First, many customer service settings involve working in teams (i.e., interdependency in delivering the service), such as a cafeteria-line food service or a nurse who records information before the patient sees a doctor. The chapter on teams elsewhere in this volume highlights many important issues that should be considered in the customer service context, and as researchers have begun to untangle the determinants of collective service performance behavior, we expect an increased focus on teams in this setting will improve our understanding both of teams and of CSB.

Second, we have mentioned several times that the customer influences CSB. Greater attention to how those outside the organization influence the behavior and attitudes of those in the organization has been occurring in CSB research, particularly with regard to emotional labor and organizational justice. Greater incorporation of the customer into job analyses for selection, training needs assessments, performance evaluation, reward and recognition systems, and other areas should proceed thoughtfully so as to ultimately lead to greater gains in CSB.

Third, given the increased use of the Internet, customer service behaviors in a virtual environment should be the focus of more research. This is especially true as the Internet has in many ways empowered customers to be more vocal, through use of online service reviews (e.g., Amazon product reviews), Facebook postings, and “reference/reputation”-focused Web sites (e.g., Angie’s List). Further, there has been exponential growth in online customer service encounters over the last decade, and yet we know little about psychological differences in service delivery between “e-tail” and traditional service encounters.

Finally, more work needs to consider the effects of turnover within customer service contexts. If, as noted above, service delivery requires teamwork, then the likely consequences and costs of turnover are considerably greater in service settings than individual-level research might suggest. For example, Shaw, Duffy, Johnson, and Lockhart (2005) showed that turnover for people more “central” in a social network causes greater disruption and more negative consequences. Kacmar, Andrews, Van Rooy, Steilberg, and Cerrone (2006) further demonstrated that manager turnover can contribute to team member turnover, which cumulatively disrupts the provision of service and ultimately business effectiveness (see Hausknecht et al., 2009, for similar findings). Given that many service occupations (e.g., retail) have turnover in excess of 60% to 70% annually, it is vital to understand how to reduce turnover and identify the consequences of turnover.

This chapter began with a discussion of the prevailing view that service is oftentimes poor and needs to be improved. The chapter discussed how applications of basic principles from I-O psychology might enhance CSB. In the time since the first version of this chapter was published, there have been some areas where significant progress has been made, particularly in the areas of emotional labor and service climate/aggregate attitudes. Yet other areas, such as the measurement of CSB, selection for CSB, or CSB job design, have seen almost no change. We

hope that this chapter helps reinforce the need for a better understanding of CSB across all academic disciplines and topics.

INTRODUCTION

The research domain generally referred to by the term *JDM* is vast and ill-bounded. It is, however, reasonably easy to identify the core concerns and issues it covers, even if one is unsure of the remote boundaries. The field has generally been concerned with choices made after some degree of deliberation: Choosing to take a particular job is included; choosing to remove one's hand from a hot burner is not. The deliberation involved includes some prediction or anticipation, of two distinct sorts: prediction of the possible consequences of alternative actions and prediction of one's evaluative reactions to these consequences. What will or might happen if I do A or B? And will I like these outcomes, or not? Selection of an action is often preceded by significant inferential effort, as when medical diagnosis precedes selection of a treatment. Substantial creative effort may be invested in generating action alternatives.

The term *judgment* often is used, imprecisely, to refer to several distinct parts of this process. The physician might use the phrase "In my medical judgment..." as a preface to a statement of what disease she thinks the patient is suffering from (diagnostic inference); what future course she expects the disease to follow (prediction or prognosis); what treatment she is recommending (decision); or what tradeoffs among risks, side effects, and prospects the patient will prefer (preferential prediction). Other topics often included under the JDM rubric are problem solving (viewing the physician as trying to

solve the puzzle of the patient's symptoms); information search (ordering tests, conducting exploratory surgery); memory (recall of earlier cases or symptom patterns); and dynamic decision making (as when the physician makes multiple interventions over time as the patient responds or fails to respond to treatments). JDM and its terminology, in short, is not neatly defined.

Given this inclusive and open-ended definition of the field and its constituent topics, we make no claim of comprehensiveness for this chapter, nor for the relative emphasis among the topics we have included. Our general goal has been to provide the reader with an introduction to the central issues in JDM, but we have been highly selective as to topics and relative emphasis. We have treated lightly or left out altogether many topics conventionally included in JDM surveys, in part by conscious (if inevitably biased) assessment of interest and research potential, in part by simple oversight. Our biases are generally toward actual or potential application rather than toward theory building per se. We note methodological issues only where they seem special to, or especially serious for, JDM. Finally, we have allowed ourselves a little scope for speculation on where the field might develop next, less in the spirit of confident prediction than in the hopes that it will spur our imaginations and those of others.

In this age of rapid and convenient electronic literature searches, we saw little point in stuffing this chapter full of exemplary citations on each topic. Other useful sources include two collections of papers sponsored by the Judgment and Decision Making Society: Goldstein and

Hogarth (1997), addressing theoretical issues, and Connolly, Arkes, and Hammond (2000), for more applications emphasis. Recent reviews of note include Dawes (1998); Mellers, Schwartz, and Cooke (1998); Highhouse (2002); and Weber and Johnson (2009). Rilling and Sanfey (2011) review recent work in neuroscience bearing on decision making, especially social decisions. Loewenstein, Rick, and Cohen (2008) survey research linking neuroscience and economics, and Dufwenberg (2006) and Battigalli and Dufwenberg (2009) do the same for studies in what is referred to as psychological game theory.

NORMATIVE/PRESCRIPTIVE VERSUS BEHAVIORAL/DESCRIPTIVE THEMES IN JDM

Perhaps more than other areas of the human sciences JDM research includes elements of both description and prescription, of trying to discover what people actually do when they form judgments and make decisions, and advising them on how they might do these things better. The advice-giving theme can be traced to mathematicians of the 18th century French court, who offered advice on such matters as the fair price for gambles (Bernstein, 1996; Stigler, 1986). The roots of the descriptive theme are more widely scattered, but were well established by the time of two landmark review papers (Edwards, 1954, 1961), which substantially launched behavioral interest in decision making.

The two themes seem to be built into the subject matter. If one starts, for example, with an interest in how a doctor makes a particularly difficult diagnosis (e.g., Einhorn, 1974), one would probably investigate the types of diagnostic information the doctor collects, the way she puts it together into an overall judgment, her ability to reproduce the same judgment on repeated cases, and so on. But it would be hard not to ask the evaluative questions: How well is she doing? Are her diagnoses correct? How well could anyone, or a computer, do in making this diagnosis from this information? How might she be helped to do it better? Conversely, a decision analyst might be able to show that, given specified preferences and probability estimates, a manager would be well advised to make a given set of investments. This still leaves open the manager's ability to state appropriate preferences and to assess required probabilities—and to generate enough faith in the entire analysis to be prepared to take action based on it. Thus, serious descriptive work on decisions often reaches important normative questions, while intendedly prescriptive studies rise or fall on the

realism with which they represent the psychology of the decision maker.

This interplay of descriptive and prescriptive issues is a central source of interest to many JDM researchers. However, it has also led to what is seen by many as an undue interest in decision errors. A major research program of the 1970s and 1980s, associated with Kahneman and Tversky (see section on heuristics and biases later in this chapter), assumes that observed decision behavior is generated by a reasonably small number of cognitive rules of thumb or *heuristics*, mental shortcuts that generally produce reasonable (and quick) results. These heuristics were demonstrated by showing that people generate systematic *errors* in specific, carefully constructed situations. The errors were defined as a deviation between what a subject did and the conclusions derived from some optimal rule—for example, a subject's probability estimate when given some information and the estimate that would be generated by Bayes's theorem in the same situation. This investigation of errors took on something of a life of its own (Edwards and von Winterfeldt, 1986; Jungermann, 1983), ignoring the facts that (a) the errors existed only if the optimal rule was, in fact, appropriate and accepted, and (b) there was little effort to assess the generality of the errors.

None of this is to suggest that humans are immune to decision error. Most of us, drawing on scientific evidence and personal experience alike, are happy to accept any help that is offered in our important life decisions. It is not clear, however, how common serious decision errors actually are. How might one assess an overall decisional batting average for the typical human, other than citing casual evidence suggesting it is not close to either 0 or 1,000? Without an agreement on what constitutes decision error, and an overall estimate of its frequency, one cannot assess how serious the biases caused by heuristic use might be. We argue only that, when presented with a normative recommendation, it is always wise to ask if its assumptions are descriptively accurate; and, when presented with a descriptive analysis of some decision maker, it is always interesting to ask how well he or she is doing.

INFERENCE PROCESSES

The Lens Model

Brunswik (1952) illustrated his discussion of visual perception with a diagram that has come to be called the Lens

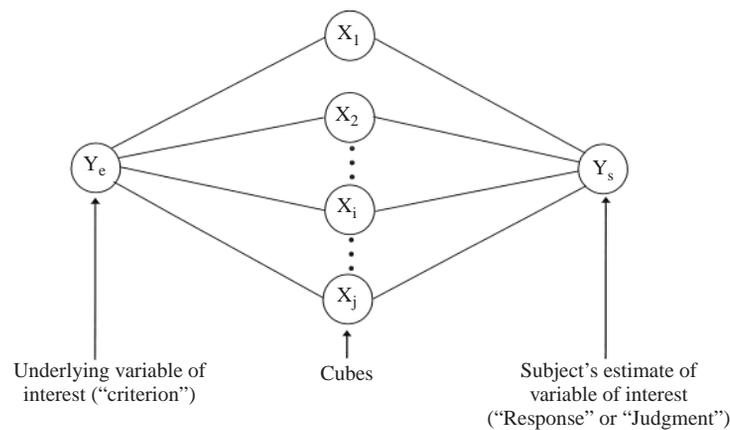

Figure 19.1 Brunswik's lens model

Model (Figure 19.1). He argued that our skill at estimating some physical quantity such as the weight or distance of an object is the result of our ability to combine various imperfect "cues" to the quantity being estimated. For example, cues for distance include image brightness and sharpness, binocular disparity, parallax, and so on. None of the cues is perfectly correlated with actual distance, but a skilled perceiver can make use of the multiplicity and redundancy of cues to achieve highly valid estimates. The "lens" terminology simply draws attention to the similarity between the process of cue generation and integration and the diverging rays of light from an object being brought into focus by a convex lens.

Hammond (1955) proposed that the same model might be used to represent judgment processes. For example, the variable of interest might be a job applicant's ability at some task, as reflected in cues such as scores on some predictive tests, reports from previous employers, and claimed experience in similar jobs. The judge's task would be to combine these imperfect cues into an overall judgment of the candidate's ability and thus into a prediction of the candidate's performance on the job.

The great value of the lens model is that it draws our attention simultaneously to the judge (represented on the right-hand side as combining cues onto a judgment) and to the environment (represented on the left-hand side as some underlying state of interest spinning off imperfect cues). Achieving good accuracy requires both that the cues be reasonably informative about the underlying variable, and that the judge use these cues in an effective way. In fact, the mathematical relationships among the cue validities and utilizations and overall achievement have been helpfully analyzed in the so-called Lens Model Equation (Tucker, 1964). The model also draws

attention to one of Brunswik's methodological precepts, the call for "representative design" (Brunswik, 1955). In essence, this requires that cue-sets presented to subjects retain the cue ranges and intercorrelations found in some specified environment. Specifically, representative design forbids use of factorial crossing of cue values, since this procedure destroys naturally occurring cue intercorrelations. This will disrupt the judge's normal judgment "policy" and may, in the limit, produce cue sets the judge finds incredible. Consider, for example, the reaction of an employer to a set of applicant records in which there was no relationship among test scores, undergraduate grade-point average, and quality of references. At least some of these applicants would probably be rejected as erroneous or fraudulent.

Multiple-Cue Probability Learning (MCPL) Studies

In more-or-less complete violation of "representative design" precepts, a large body of research has emerged broadly addressing subjects' abilities to learn to use probabilistic information. The general format is to present the subject with a (long) series of trials in each of which several cues are presented and the subject is asked to predict the value of some criterion variable to which the cues are related. After the subject makes an estimate, he or she is told the correct answer before proceeding to the next trial. Such a format lends itself to endless variations in task characteristics: number of cues presented, their validity, the functional form of their relationship to the underlying variable the subject is to estimate, the quality of feedback presented, whether or not the task is embedded in a meaningful verbal context, whether or not learning aids are provided, and so on.

The evidence from dozens of such studies is that, except for the simplest versions, these MCPL tasks are very hard to learn. *Simple* generally means one or two cues, strongly and linearly related to the criterion, under conditions of low feedback error. For example, Slovic (1974) used a task with one linear cue that correlated 0.80 with the criterion, and found subject estimates approaching maximum possible performance in the last of 100 trials. However, when the cue validity was -0.80 , learning after 100 trials was less than half this level. Deane, Hammond, and Summers (1972), using a three-cue task, found reasonable learning after 150 trials when all three relationships were positive, but almost no learning when the relationships were U-shaped. Learning improves somewhat when the subjects are warned about possible nonlinearities (Earle, 1970). Two-cue interactions are learned only if helpful verbal cues are provided (Camerer, 1981). Even after reaching high levels of performance under low-error feedback, subjects' performance rapidly declines when feedback error levels are increased (Connolly & Miklausich, 1978). In short, as Klayman (1988) suggests, learning from outcome feedback is "learning the hard way."

In many real-world tasks, of course, feedback is probably much *less* helpful than the "outcome feedback" provided in these MCPL laboratory tasks. A human resource professional trying to learn how to predict a candidate's performance on the job from application materials receives feedback only after significant delay (when the applicant has been hired and on the job for some time); under high error (supervisor ratings may introduce new sources of error); and, crucially, only for those applicants actually hired (see Einhorn, 1980, on the inferential problems facing waiters who believe that they can spot good tippers). Laboratory MCPL tasks show excruciatingly slow learning of simple tasks under relatively good outcome feedback. Real-world tasks are almost certainly more difficult, and real-world feedback almost certainly less helpful, than the laboratory conditions. It thus seems unlikely that outcome feedback is the key to learning real-world tasks of this sort and interest in laboratory MCPL studies seems to have largely subsided in recent years.

Policy Capturing

Policy capturing, also known as *judgment analysis* (Stewart, 1988), is the process of developing a quantitative model of a specific person making a specific judgment. The general form of such a model is an equation, often first-order linear, relating the judgments, J , to a weighted

sum of the information "cues," x_i . Hundreds of such studies have been conducted, dating at least to Wallace (1923), who modeled expert judges of corn. Hammond and Adelman (1976) studied judgments of handgun ammunition, Slovic (1969) studied stockbrokers, Phelps and Shanteau (1978) studied hog judges, and Doyle and Thomas (1995) studied audiologists. In addition, policy capturing has been commonly used for organizational applications, such as decisions concerning salary raises (Sherer, Schwab, & Heneman, 1987), alternative work arrangements (Powell & Mainiero, 1999), cross-cultural differences in non-monetary compensation decisions (Zhou & Martocchio, 2001), and applicant ratings and recommended starting salaries (Hitt & Barr, 1989). Policy capturing is thus a very widely used procedure.

It is also fair to say that the technique has been widely abused, and that many of the findings are hard to assess or interpret. The basic approach is so simple and obvious that it is easy to overlook some important subtleties that vitiate the final conclusions. We shall sketch some of these points here; see Stewart (1988) and Brehmer and Brehmer (1988) for fuller discussion, and Karren and Barringer (2002) for a focus on organizational studies using this methodology.

Suppose one were interested in modeling the judgment process of a university department head selecting candidates for graduate school. The department head reads an applicant's file, writes a merit score between 0 and 100 on the cover, and moves to another file. At a later stage, the files are rank-ordered and applicants are admitted in descending order of merit score until all the places are filled. How might one model the department head's judgment process?

A first step is to establish what information she is collecting from each file: the cues. Simply asking her what cues she is using may be misleading: It is possible that she is biased toward (or against) women, minorities, left-handers, or Scrabble players and is either unaware of the fact or chooses not to admit it. Second, how does she code this information? What counts as a "strong" grade-point average or an "acceptable" letter of reference? Significant work may be needed to translate the department head's inspection of the file into a set of scale scores representing the cues she discovers and scores in it. Stewart (1988) provides helpful practical advice on this process, and Brehmer and Brehmer (1988) discuss common failures. Doyle and Thomas (1995) report an exemplary procedure for identifying cues, in their case cues used by audiologists in assessing patients for hearing aids. Once cues and judgments have been identified and scored, estimation of a standard multiple linear regression model is

straightforward. Interpretation, however, may not be. In particular, the interpretation of the relative weights given to each cue is conceptually difficult (see Stevenson, Busemeyer, & Naylor, 1991).

One subtle (and, in our view, unsolved) problem in policy capturing is how to meet Brunswik's goal of representative design. This goal plainly prohibits constructing simple orthogonal designs among the cues: Such independence destroys patterns of cue intercorrelations on which expert judges may rely. Cue ranges and intercorrelations should reflect those found in some relevant environment, such as the pool of applicants or patients with whom the expert regularly deals. A sample of recent actual cases would appear to meet this requirement, but even here complexities arise. If one wishes to compare expert predictions with actual performance, then only the subset of applicants hired or admitted is relevant—and this subset will have predictably truncated cue ranges and intercorrelations compared to the entire pool. Changes in pool parameters arising from changes in the employment rate, prescreening, self-selection into or out of the pool, or even of educational practices may all affect the modeled judgment. The underlying problem of what exactly defines the environment the sample of cases is intended to represent is a conceptually subtle and confusing one.

Given these methodological worries, some caution is needed in summaries of research findings. Common generalizations (Brehmer & Brehmer, 1988; Slovic & Lichtenstein, 1971) include:

- Judges generally use few cues, and their use of these cues is adequately modeled by simple first-order linear models.
- Judges describe themselves as using cues in complex, nonlinear, and interactive ways.
- Judges show modest test–retest reliabilities.
- Interjudge agreement is often moderate or low, even in areas of established expertise.

In light of the methodological shortcomings noted above, we propose that such broad generalizations be taken as working hypotheses for new applications, not as settled fact.

Heuristics and Biases

Edwards (1968) ran the following simple experiment. He showed subjects two book bags containing 100 poker chips. Bag A contained mainly red chips, Bag B mainly black. He randomly chose one of the bags, drew out a

small sample of chips, and showed them to the subjects. He then asked the subjects for their estimate of how likely he was drawing from Bag A. He found that subjects, initially persuaded that the probabilities were 50–50 before seeing the sample, generally revised their estimates in the direction suggested by the sample (i.e., toward A, if the sample was mainly red chips) but not as far as would be required by Bayes's theorem. Edwards labeled the phenomenon *conservatism*. It involves three elements: a well-structured probabilistic task (e.g., sampling from two known populations); a sensible normative model for how the task should be performed (Bayes's theorem); and an observation that actual behavior is systematically biased with regard to this normative model.

The dominant paradigm for research on judgment under uncertainty through the 1970s and 1980s, the so-called heuristics and biases paradigm (Tversky & Kahneman, 1981), was founded on observations of systematic errors of this sort: probabilistic tasks in which human behavior deviated systematically from a normative rule. The paradigm was, however, more than a simple catalog of errors. Tversky and Kahneman argued that the observed errors were manifestations of cognitive rules of thumb or *heuristics*, which, though generally effective and low cost, can be misleading in certain unusual circumstances. Thus, for example, we might guess the relative popularity among our acquaintances of various hobbies by noting the ease or difficulty with which we could bring examples to mind (the *availability heuristic*). This might work pretty well for most hobbies, but would likely mislead us for embarrassing or illegal hobbies, whose practitioners might well take pains to conceal their interest, or for praiseworthy hobbies, about which people would be likely to boast. Similarly, dramatic causes of death are judged to be commoner than less dramatic ones (Slovic, Fischhoff & Lichtenstein, 1979), and easily found words as more likely than those more difficult to search for (Tversky & Kahneman, 1973). (We discuss examples of heuristics and biases in prediction more fully in the following section.)

Work in this paradigm has declined in recent years. First, whatever the theoretical intentions, much of it became an ever-growing catalog of errors, with modest or no theoretical underpinnings that might allow prediction of when a particular heuristic would be evoked or error displayed. Second there was growing doubt about the appropriateness of some of the normative models invoked to demonstrate that errors had been made. Third, it became clear that at least some of the claimed “errors” were actually the result of subjects working successfully on problems other than the one the experimenter intended.

(See Jungerman, 1983, and Gigerenzer, 1991, for extended critiques of the heuristics and biases approach.) Research interest in documenting our shortcomings seems to have declined. Increasingly researchers are exploring the actual mechanisms that account for our performance, including the sometimes excellent performance of experts in real settings. (See Goldstein & Hogarth, 1997, and Connolly et al., 2000, for recent samplings of the literature.)

PREDICTION

Simple Prediction

There is evidence that, in making predictions, we use a variety of the heuristics discussed earlier. We will discuss three such heuristics: anchoring and adjustment, availability, and representativeness.

Imagine that an organization wants to predict sales for the coming quarter. A common approach would be to start with current sales as an initial estimate (the “anchor”), and then make an adjustment to account for market trends, new incentives, and so on. While this anchor-and-adjust heuristic may provide a reasonable estimate, research indicates that two potential problems may arise. First, the anchor may not be appropriate: If a new motivation program is applied to only a subset of salespeople, then the average of this group’s sales should be used as an anchor, rather than the average of all salespeople. Second, adjustment from the anchor may not be sufficient: The predicted value may be too close to the anchor of average sales. Bolger and Harvey (1993) found that decision makers used an anchor-and-adjust strategy for predicting events over time (e.g., sales) and that their adjustments were insufficient. Epley and Gilovich (2006) suggest that the underlying mechanism is inadequate search effort, at least when the initial anchor is generated by the individual, and may be overcome by incentives and forewarnings.

Another method for making predictions uses the “availability” heuristic discussed earlier: The likelihood of an event is judged by how easily instances come to mind through either memory or imagination. A manager may predict how likely a particular employee is to be late for work based on recollections of past episodes. However, availability may lead to biased predictions when we selectively attend to information that is available (e.g., a vivid or recent event) rather than consider historical/statistical data systematically. For instance, people who had recently experienced an accident or a natural disaster estimated

similar future events as more likely than those who had not experienced these events (Kunreuther et al., 1978). Similarly, managers conducting performance appraisals can produce biased evaluations (either positive or negative) when they rely on memory alone: Vivid episodes and events within 3 months prior to the evaluation are overweighted relative to other information (Bazerman, 1998). However, recent research suggests that people may be able to discount the biasing effect of availability when the cause of the bias is obvious to them (Oppenheimer, 2004; Sjöberg & Engelberg, 2010)

A third heuristic used in prediction is representativeness, in which the likelihood of an event is judged by its similarity to a stereotype of similar events. The “gambler’s fallacy” (for example, expecting a run of heads to compensate for an observed run of tails) appears to rely on the (false) belief that small samples of random events should accurately reflect or be similar to the properties of the underlying distribution. Thus, a manager might predict the success of an employee by how similar he is to other known successful employees. Again, while this is generally a good initial estimate, using the representativeness heuristic can lead to systematic biases. First, people have a tendency to make nonregressive predictions from unreliable predictors—that is, to expect extremely high (or low) outcomes when the predictor is extremely high (or low). For example, Tversky and Kahneman (1974) attempted to teach Israeli flight instructors that positive reinforcement promotes learning faster than negative reinforcement. The flight instructors objected, citing examples of poor performance following praise and improved performance after reprimands. The instructors were attributing fluctuations in performance to interventions alone and not recognizing the effect of chance elements. Those trainees who received praise had performed at a level above their average performance, while those who were reprimanded had performed below their average. Statistically, both groups should tend to perform closer to their average performance on subsequent flights. Thus, the flight instructors falsely concluded that praise hurts and reprimands help because they predicted, by representativeness, that performance should be similar to the previous episode rather than regressing their predictions of performance to the mean. A parallel fallacy arises when we predict that the best-performing salesperson this year will be the top performer next year. Similar biases have been observed in stock market investment where, despite repeated warnings, investors seem to expect a stock’s previous performance to be highly predictive of its future performance (Chen, Kim, Nofsinger, & Rui, 2007; Rabin, 2002).

Another bias that has been attributed to using the representativeness heuristic is the tendency to neglect base rates or the prior probabilities of outcomes (Kahneman & Tversky, 1973). Imagine that a company knows that a small percentage (say 1%) of its employees is using illegal drugs. The company conducts a random drug test in order to determine which employees are using drugs and are subject to termination. The test is relatively accurate, being correct 90% of the time; that is, the test will be incorrect only 10% of the time when either a drug user tests negative (“false negative”) or a nonuser tests positive (“false positive”). Should the company fire employees who test positive for drugs? Most would say yes, thinking that the probability of being a drug user given the positive test result should reflect the accuracy of the test (90%). In fact, it is very *unlikely* ($p = 8.3\%$) that a person testing positive in this story is a real drug user. Although the test is relatively accurate, there are so few real users that most of the positive tests will be false positives. If we ignore the low base-rate of drug use, we hugely overestimate the test’s accuracy in identifying actual users. A similar example in a legal context, the so-called cab problem, is discussed by Kahneman and Tversky (1973).

Overconfidence

There are other potential problems in making predictions. In some situations, our judgments are overconfident. Experiments demonstrating overconfidence often ask difficult almanac questions in which subjects either choose between two options (e.g., “Which river is longer, the Tigris or the Volga?”) or state a range of values within which they are 90% confident a true value lies (e.g., “How long is the Tigris river?”). Klayman, Soll, Gonzalez-Vallejo, and Barlas (1999) found general overconfidence for almanac questions, but much more overconfidence for subjective confidence intervals than for the two-choice questions (approximately 45% vs. 5%). They found significant differences between individuals, but overconfidence was stable across individuals answering questions from different domains (e.g., prices of shampoo and life expectancies in different countries). A person who was overconfident in one domain was likely to be overconfident in another. Barber and Odean (2001) found men to be more overconfident than women in investment decisions. Men, as a result, traded more often and made less money than did women. Simon and Houghton (2003) found similar overconfidence, and significant financial losses, in managers’ new-product decisions. Overconfidence has been found in many, though not all, contexts

(Moore & Cain, 2007; Yates, 1990). There is evidence that it declines with experience (Keren, 1987), and with instructions to think of ways in which an estimate might be wrong (Fischhoff, 1982). Overconfidence and its control has obvious implications in such organizational contexts as hiring, estimating timelines and costs, and developing business strategies.

There are also problems with learning from experience to make better predictions. The hindsight bias (Fischhoff & Beyth, 1975) hinders us in learning from our mistakes. In retrospect, we believe that we knew all along what was going to happen, and are unable to fully recover the uncertainty we faced before the event. This impedes learning the real relationships between decisions and outcomes that are necessary for good predictions. Unfortunately, simply warning people of this bias does not help, though inducing them to think of reasons they may be wrong can reduce the effect (Fischhoff, 1977). (Marks & Arkes, 2010, describe a new procedure based on source confusion that may help debiasing.) In addition, we may not seek the necessary information to test our beliefs since we have a tendency to seek confirming evidence (also called the *confirmation bias*; Wason, 1960) rather than disconfirming evidence. (See the section on information search, information purchase.) Finally, the structure of the environment may not readily provide information to test relationships since some information is naturally hidden. For example, personnel selection is often based on human resource test scores whose correlations with future job performance may be low. This will be true even for valid predictors of performance. We hire only applicants with high scores, so the variance of test scores for those hired is low and any variation in job performance will likely be due to other factors (e.g., motivation, training, random elements). We generally do not observe the performance of those we do not hire—data essential to testing the validity of our predictions.

Idea Generation

Before an outcome’s likelihood can be assessed, it must first be identified as a possibility. There is good evidence that we do not routinely generate many of the possible outcomes that may flow from our actions (Gettys & Fisher, 1979), and numerous remedial techniques have been proposed. One popular approach, group brainstorming, was first proposed in a nonacademic book (Osborn, 1953) as a way to generate as many ideas as possible. The participants were encouraged to improve, combine, and “piggyback” off other ideas without criticism in order

to generate more ideas than working individually. While this approach is intuitively appealing, subsequent research (McGrath, 1984) has shown that compared to brainstorming groups, the same number of individuals working alone (called *nominal groups*) produce more ideas with the same level of quality. Diehl and Stroebe (1987) concluded that the main reason appears to be production blocking: Since only one group member can talk at a time, the other members may forget their ideas, construct counterarguments, and so on in the meantime.

In the 1980s, computerized technology was developed to aid group brainstorming and decision-making processes (fortunately ignoring the evidence discussed above!). One popular system consists of several networked computers with a common main screen that can be seen by all in the room (Connolly, 1997; Nunamaker, Dennis, Valacich, Vogel, & George, 1991). Group members type ideas on their computers, and interact by passing files between machines. All members can thus be productive simultaneously, while drawing stimulation from reading and adding to one another's files. This form of interaction appears to overcome the problems of face-to-face (F2F) brainstorming. Electronic brainstorming (EBS) groups can outperform equivalent nominal groups (Valacich, Dennis, & Connolly, 1994), at least when the EBS groups are large (approximately eight or more). It is not entirely clear why large EBS groups enjoy this advantage in idea generation (Connolly, 1997). Anonymity provided by the EBS system increases the number of ideas produced (Connolly, Jessup, & Valacich, 1990) and the number of controversial ideas (Cooper, Gallupe, Pollard, & Cadsby, 1998), but may decrease satisfaction with the task (Connolly et al., 1990). Several recent meta-analyses continue to provide evidence for the superiority of EBS over FTF brainstorming in terms of idea generation (Dennis et al., 2001; Dennis & Williams, 2005; DeRosa, Smith, & Hantula, 2007).

Interestingly, businesses continue to use F2F group brainstorming even though the literature clearly shows that it is inferior to both nominal groups and EBS. One reason may be its strong intuitive appeal. Paulus, Dzindolet, Poletes, & Camacho (1993) found that subjects predicted future performance and perceived actual performance as better in F2F brainstorming groups than in nominal groups, when in fact performance was superior in the latter. Another reason for the popularity of F2F brainstorming is the lack of access to EBS equipment. There is also some evidence that the performance of F2F groups can be raised to that of nominal groups by using highly trained facilitators (Oxley, Dzindolet, & Paulus, 1996). Kavadias and Sommer (2009) argue that the relative

effectiveness of nominal and interacting groups is a function of both how structured the problem is and how diverse the group's skills are. However, it may be that what researchers study (i.e., quantity and quality of idea generation) is not what business managers want (i.e., group well-being and member support). Dennis and Reinicke (2004) provide evidence that business managers use F2F brainstorming since it is superior in improving group well-being and member support and are less concerned with the increased idea generation capability of EBS.

PREFERENCES

Values, Goals, and Objectives

The idea of preference is fundamental to the idea of purposive choice: We prefer some possible outcomes to others and try to select actions accordingly. This is not the same as the claim that people "have" values (or preferences, goals, purposes, desires, etc.), in the sense that they can instantaneously say which of two real or imagined states they prefer at a given moment. As Fischhoff (1991) points out, some researchers (e.g., economists, opinion pollsters) behave as though people have fully articulated preferences for all possible objects and states of being, while others (e.g., decision analysts) suppose that we have only a few, basic values and must derive or construct preferences from these for most unfamiliar choices. An articulated values theorist might study a series of hiring decisions with a view to inferring the relative importance a particular human resource (HR) manager gives to different candidate attributes, such as experience, age, and gender. In the same context a basic values theorist might work with the manager to improve the accuracy or consistency with which her values are applied to future hiring decisions. (Indeed, it is possible to imagine doing both studies with the same manager, first capturing her "policy" from a series of earlier decisions, and then applying them routinely to subsequent decisions, a form of decision aiding called *bootstrapping*.)

Whichever view of valuing one assumes, there is plenty of evidence to indicate that the process can be imperfectly reliable and precise. Preferences for alternative medical treatments can shift substantially (for both patients and physicians) when the treatments are described in terms of their mortality rates rather than their survival rates (McNeil, Pauker, & Tversky, 1988). Subjects asked how much they would be prepared to pay to clean up one, several, or all the lakes in Ontario offered essentially the

same amount of money for all three prospects (Kahneman, Knetch, & Thaler, 1986). Simonson (1990) found that people's preferences for different snacks changed markedly from what they predicted a week ahead and what they chose at the time of consumption. Strack, Martin, and Schwartz (1988) found that students' evaluation of their current life satisfaction was unrelated to a measure of their dating frequency when the two questions were asked in that order, but strongly related ($r = 0.66$) when the dating question was asked first. Apparently, the evaluation of one's life overall is affected by the aspects one is primed to consider. MBA students' ratings of their satisfaction with and the fairness of potential salary offers were markedly influenced by the offers received by other students in their class (Ordóñez, Connolly, & Coughlan, 2000). As these examples suggest, measures of preferences for real-life entities are sensitive to issues of framing, timing, order, and context and a host of other influences. It is unclear whether the problems are primarily those of imperfect measurement or of imperfect development of the respondent's values and preferences themselves.

A common assumption of basic values researchers is that complex value structures are organized in the form of hierarchies or *value trees* (e.g., Edwards & Newman, 1982). The HR manager, for example, might consider a candidate's attractiveness in terms of a few high-level goals, such as "job knowledge," "motivation," and "growth potential," and assign some importance to each. At a lower level, these attributes would be decomposed so that "job knowledge" might include scores for formal education, job experience, and recent training, and so on. Such trees help to connect high-level values to lower level operational measures. More complex interconnections among value elements are also possible (see, for example, Keeney, 1992).

Utilities and Preferences

The term *utility* is used in two different ways in JDM. In the formal, mathematical sense (Coombs, Dawes, & Tversky, 1970), utilities are simply a set of real numbers that allow reconstruction or summary of a set of consistent choices. The rules for consistency are strict, but appear perfectly reasonable. For example, choices must be "transitive," meaning that if you choose A over B and B over C, then you must also choose A over C. Situations in which thoughtful people wish to violate these rules are of continuing interest to researchers (Allais, 1953; Ellsberg, 1961; Tversky, 1969). Utilities, in this sense, are defined

in reference to a set of choices, not to feelings such as pain and pleasure.

A very powerful formulation of this choice-based view of utility (von Neumann & Morgenstern, 1947) relies on the idea of "probabilistic in-betweenness." Suppose A is (to you) the "best" in some choice set, and C is the "worst." You like B somewhere in between. von Neumann and Morgenstern suggest that you would be prepared to trade B for a suitable gamble, in which you win (get A) with probability p and lose (get C) with probability $(1-p)$. You could make the gamble very attractive by setting p close to 1.0, or very unattractive by setting it close to 0.0, so, since you value B in between A and C, one of these gambles should be worth the same to you as B itself. The value of p at which this happens is your "utility" for B, and expresses your preference for B in an unambiguous way.

The beauty of this approach is that it allows a decision maker to evaluate every outcome on a decision tree by the same metric: an equivalent (to her) best/worst gamble. Further, if some of these outcomes are uncertain, their utility can be discounted by the probability of getting them—their "expected utility." If I value some outcome at 0.7 (i.e., as attractive to me as a best/worst gamble with 0.7 to win, 0.3 to lose), then I'd value a toss-up at that same outcome at (0.5×0.7) or 0.35. This provides a tight logic for expected utility as a guide to complex choices.

It is not clear how closely this formal view of utility conforms with the experience or anticipation of pleasure, desire, attractiveness, or other psychological reactions commonly thought of as reflecting utility or disutility. Indeed, the introduction of a gambling procedure for measurement gives many people problems, since it seems to involve elements of risk as well as outcome preferences. Many people turn down bets such as (0.5 to win \$10, 0.5 to lose \$5), despite their positive expected value (EV) $(0.5 \times \$10) + (0.5 \times -\$5) = \$2.50$, in the example). Why? One possibility is declining marginal utility: The \$10 gain offers only a modest good feeling, while the \$5 loss threatens a large negative feeling, so the 50–50 chance between the two is overall negative. This is referred to as *risk aversion*, though it may have little connection to the actual churn of feeling the gambler experiences while the coin is in the air.

The psychology of risk—what is seen as risky, how risk is talked about, how people feel about and react to risk—is a vast topic, beyond the scope of this brief chapter. Many studies (e.g., Fischhoff, Lichtenstein, Slovic, Derby, & Keeney, 1981; Peters & Slovic, 1996) raise doubts about our ability to assess different risks, and

show very large inconsistencies in our willingness to pay to alleviate them (Zeckhauser & Viscusi, 1990). Public policies toward risk are hampered by large discrepancies between expert and lay judgments of the risks involved (Fischhoff, Bostrom, & Quadrel, 1993; Slovic, 1987, 1993). The notion of risk aversion or risk tolerance as a stable personality characteristic guiding behavior across a range of situations finds little empirical support (Lopes, 1987). Recent brain-imaging work (e.g., Tom, Fox, Trepel, & Poldrack, 2007) has started to probe the neurological processes underlying risk taking and loss aversion.

Comparison Processes

The ideas we have reviewed so far all associate preference or value with an outcome in isolation from others. That is, they suppose that a specific outcome has a specific utility to a specific decision maker. Both casual reflection and careful research show that this assumption is false. One's feelings about a \$3,000 pay raise, for example, might shift significantly if one discovered a rival had made more, or less; if one expected nothing, or \$5,000; or if it was given for merit rather than as a cost-of-living adjustment. Comparison processes of various sorts influence the value we attach to options and outcomes.

Inter-outcome comparisons are central to recent theories of regret and disappointment, which we will review below. Comparisons are also central to equity theory (Adams, 1965; Walster, Berscheid, & Walster, 1973), in which an outcome's value is modified by the recipient's judgment of whether or not it was fair. According to equity theory, equity is achieved when the ratio of outputs (e.g., salary, benefits, rewards, punishment) to inputs (e.g., hours worked, effort, organizational citizenship behaviors [OCBs]) is the same for all individuals being considered. Thus, in order to determine if equity is achieved, a comparison other (e.g., a coworker) is required. Early studies investigated equity theory by placing subjects in an experimental work context in which they received payment for the amount of work completed. Subjects were informed about the pay given to other, similar workers. Research results have strongly supported equity theory predictions (Greenberg, 1982). Equity imbalance was restored in a manner consistent with equity theory: Underpaid workers decreased their performance (i.e., lowered their inputs), whereas overpaid workers increased their performance (increasing inputs). In an interesting field study (Greenberg, 1988), workers were temporarily reassigned to offices that were either of higher or lower status

than their regular offices. Consistent with equity theory, those assigned to higher status offices increased their performance, whereas those in lower status offices decreased their performance.

Choice Rules

In almost every practical choice situation, each of the options being considered has a number of features, attributes, or dimensions that affect its worth to the decision maker. A job, for example, might be defined in terms of such dimensions as salary, location, interest of work, promotion possibilities, and so on. Researchers have proposed a number of alternative models to describe the process by which decision makers choose between such multiattribute alternatives.

Multiattribute Utility Theory (MAUT) models suppose that what people do (or, in the prescriptive use, should do) is to evaluate each attribute of each alternative, add the resulting utilities into an overall utility for each alternative, and choose the alternative with the highest total. This is referred to as a *compensatory* model, in the sense that an improvement on one attribute can compensate for or trade off against a loss on another. (We discuss decision-aiding procedures for making these tradeoffs in the following section.) Some authors (e.g., Edgell & Geisler, 1980) have proposed modifications of the basic MAUT models (called random utility models) to reflect the fact that subjects' preferences are not always stable from one occasion to another.

Conjunctive models reflect preferences of the screening type, such as an army physical examination. A candidate with flat feet, for example, would be rejected regardless of how well he or she scores on other measures of physical fitness. These models are thus noncompensatory, in the sense that more on one attribute may not make up for less on another: Any low attribute value makes the entire alternative low value. An early conjunctive model, the satisficing rule, was proposed by Simon (1955). Simon argued that, in real settings, MAUT procedures make unrealistic demands on a decision maker's time and attention. Instead, decision makers search for an alternative that is acceptable on all important dimensions, and stop their search with the first such alternative. Note that this again introduces an element of probabilism into the choice, in that the order in which alternatives are considered may determine which of several acceptable options is found first. (Simon also argued that aspiration levels may change as search proceeds, adding a second element of probabilism.)

Lexicographic (dictionary-like) models rely on sequential comparisons between alternatives. Options are compared first on the modest important attribute and, if they differ, the winning option is chosen. If they tie, the next most important attribute is considered, and so on, until a winner is found. Another version of this, called the Elimination by Aspects (EBA) model, selects an attribute (or “aspect”) at random and eliminates from consideration any option that fails to reach threshold on this attribute. The process continues until only one option remains, and it is then chosen. (Note that neither of these processes is compensatory: Overall attractive options may be eliminated by a loss on an early comparison.)

Additive difference models (Tversky, 1969) assume that the decision maker compares alternatives along one dimension at a time, storing the sum of the differences favoring one alternative over the other. Probabilistic versions of this rule have also been proposed, in which comparison terminates when one alternative reaches some threshold of cumulative advantage over the other.

A number of authors (Beach & Mitchell, 1978; Payne, Bettman & Johnson, 1993) have suggested that the combination rule a decision maker uses represents a trade-off between effort and accuracy. The fully compensatory MAUT rule allows the fullest consideration of all attributes and values, but requires extensive information-processing effort. Other rules are less effortful, but do not guarantee that the best option will be chosen.

DECIDING: SINGLE-CHOICE EVENTS

Subjective Expected Utility Theory

The previous section discussed determining preferences among riskless options. However, selecting among risky options in which outcomes occur with some probability is even more difficult. For example, a firm may have to select between a set of new products to develop, each with probabilities of profits and losses. One of the simplest ways of placing a value on a risky proposition is by calculating its expected value (EV), which is the sum of each outcome multiplied by its associated probability (i.e., $EV = \sum p_i x_i$). A new product with a 75% chance of making \$15 million in profits and a 25% chance of failing, with a loss of a million in development costs would have an $EV = 0.75 * (15M) + 0.25 * (-1M) = \11.75 million in expected profits. This is the amount of money the firm would make on average if they repeatedly marketed new products with these probability/outcome characteristics.

Clearly, such a calculation would be an imperfect guide to decision making in any single case.

It can be easily shown that our preferences for risky propositions are not always consistent with an EV model. For example, how much would you pay for a gamble in which you flip a coin until the first head appears (on the n th flip) and pays $(\$2)^n$? If you get two tails followed by a head, you would receive $2^3 = \$8$. Most people offer less than \$4 to play this game. However, this game actually has an infinite EV, and according to the EV model you should be willing to pay as much as you are able. (The EV for the game is $\sum p_i x_i = \sum (1/2)^n 2^n = (1/2)\$2 + (1/4)\$4 + (1/8)\$8 + \dots (1/\infty)\infty = \$1 + \$1 + \$1\dots$)

Daniel Bernoulli (1738/1954) used the previous example (known as the St. Petersburg Paradox) to infer that people do not value a prospect in terms of the objective value of the outcomes, but on their subjective values or utilities. This model also explains why you might prefer \$50 for sure over a gamble with a 50% chance of winning \$100 and a 50% chance of \$0 (a gamble with an EV of \$50). Thus, the model of value is changed from EV with purely objective values of outcome value (x) to the expected utility, EU, with subjective values (utilities) of outcomes, $u(x)$ $EU = \sum p_i u(x_i)$.

Later, Savage (1954) went a step further and proposed subjective measures of probability, too [i.e., subjective probabilities $s(p)$], so that prospects were valued at their Subjective Expected Utility (SEU) [$SEU = \sum s(p_i) u(x_i)$]. This model provided a way of placing value not only on risky events with monetary outcomes but also on uncertain events based on the degree of belief that an event will occur. SEU expanded the application of decision theory to include a much broader range of decisions.

Prospect Theory

Although EUT provides a good normative model of choice, several studies have demonstrated the theory's weaknesses as a descriptive model of valuation and choice. The empirical violations of the axioms call into question the general applicability of EUT. For example, Tversky (1969) showed that, in certain problems, people consistently violate the transitivity axiom. The Allais Paradox (Allais, 1953) is a famous demonstration of how another EUT axiom (called *Independence*) is violated by many people.

Prospect Theory (Kahneman & Tversky, 1979) was developed to model how risky propositions are valued while accommodating decision behavior such as the Allais Paradox. The model uses the same general form

as EUT, but modifies the outcome value and probability functions to be more psychologically descriptive. A value of a prospect is defined as $\sum v(x_i)\pi(p_i)$ where $v(\cdot)$ and $\pi(\cdot)$ are the value and decision weight functions, respectively.

The decision weight function, while similar to the subjective probability function of SEU, introduces new psychological features to subjective probability. One feature is that low probabilities are overweighted and high probabilities are underweighted. For example, Lichtenstein, Slovic, Fischhoff, Layman, and Combs (1978) have shown that people tend to judge low-probability health risks (e.g., botulism) higher than the objective values but tend to underestimate higher probability health risks (such as heart disease). Another feature of the decision weight function is that it is nonlinear. While objective probabilities sum linearly, decision weights do not. For example, $\pi(.9) - \pi(.89) \neq \pi(.01)$.

In a second modification of EUT, Prospect Theory proposed a value function that was a significant departure from the previous utility functions (Figure 19.2). First, instead of defining subjective value with respect to overall wealth, the Prospect Theory value function defines value with respect to a reference point, often the status quo. Second, the value function for the domain of losses (below the reference point) is steeper than for gains. This leads to a result called loss aversion in which losses are more painful than equal magnitude gains are pleasurable. Finally, the value function is concave (risk averse) above the reference point, convex (risk seeking) below it. Since identical options can often be described in terms of

different reference points, this raises the possibility that different ways of describing the same problem may shift choices from risk seeking to risk averse. This general framing problem is discussed in the following section.

Framing

To illustrate framing Hogarth (1987) presented MBA subjects with a choice between a riskless option, A, and a risky option, B with an EV equal to A. When the options were described in terms of money saved, A was preferred. When they were described in terms of losses, however, B was preferred. Due to the differing shapes of the value functions for the domains of gains and losses, people are risk averse when options are framed positively and risk seeking when options are framed negatively.

Another type of framing, attribute framing, has been shown for riskless options. For example, Levin and Gaeth (1988) showed that subjects evaluated ground beef more favorably when it was described as 75% lean than as 25% fat (though this advantage drastically diminished after consumers tasted the beef). The credit card lobby insisted on using the label “cash discount” rather than “credit card surcharge” when gas stations charged higher prices for customers using their credit cards instead of cash (Thaler, 1980). Levin, Schneider, and Gaeth (1998) provide a useful taxonomy of different framing effects. A study by Kuvaas and Selart (2004) suggests that such effects may result from negative framing stimulating more thorough and effortful information processing rather than simply changing the valence of the different outcomes.

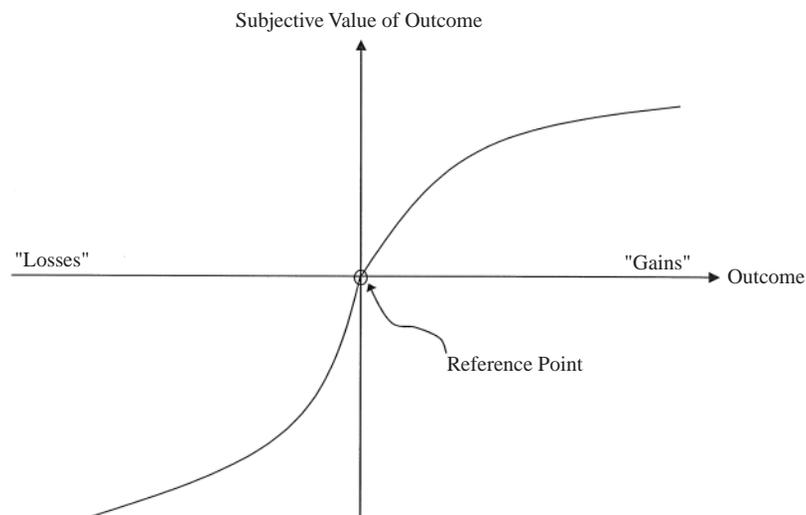

Figure 19.2 Prospect Theory's value function

Non-SEU Models of Decision Making

Most of the decision models discussed to this point have been variants on the expected value or expected utility model. They assume that a decision maker's overall evaluation of some option is formed by an evaluation of the possible outcomes flowing from the option, discounting these evaluations to reflect the uncertainty of their occurrence, and then adding these discounted evaluations together to form the overall evaluation. From EV to Prospect Theory, the guiding spirit is evaluate, discount, and add. In this section, we look briefly at three models that do not follow this format.

Image Theory (Beach, 1990, 1993) sees the decision maker as concerned to maintain consistency among three mental images: a value image (summarizing her values and beliefs about rightness); a trajectory image (summarizing her goals and a path to their attainment); and a strategic image (a set of plans that guide tactical behavior toward the goals). The theory emphasizes screening of decision options for compatibility with the decision maker's value image, and the selection of options to maintain consistency between the strategic and trajectory images. Actual comparative evaluation of options against one another (the "profitability test") occurs only in the relatively rare case in which several options survive screening. Much of the research to date has focused on this screening process (Beach, 1998), with major emphasis on the number of "violations" an option must incur before it is rejected. There has been relatively little research on the nature and stability of the images themselves (Dunegan, 1993).

A second nontraditional decision model is presented by Lopes (1987, 1995) under the somewhat ungainly title of "security-potential/aspiration" (SP/A) model. The core intuition guiding the model is that assessment of an uncertain prospect such as a gamble generates a conflict between the downside or worst-case outcome(s) and the upside or best-case outcome(s). Some individuals (security minded) tend to be primarily concerned with the downside possibilities; others (potential minded) tend to be primarily concerned with the upside possibilities. For example, offered a choice between two gambles of equal EV, one with outcomes tightly clustered, the other with gambles widely distributed, the security-minded person will prefer the tight clustering (since the possibility of large losses is smaller) while the potential-minded person will prefer the wide distribution (since the possibility of large gains is larger). This basic balancing act is modified by the subject's "aspiration level," a level of gain

or loss which the subject hopes to do better than. The model is consistent with a wide range of data, both from choices between gambles and from verbal protocols collected while making those choices. The SP/A model is a full alternative to Prospect Theory—and, indeed, does a better job of accommodating some of the evidence (Schneider, 1992).

A third non-SEU model has emerged from what is called the *Naturalistic Decision Making* (NDM) movement, which has been concerned with studying expert decision makers in their natural settings. These settings are often complex, time pressured, highly uncertain, high stakes, and dynamic, and thus unfriendly to thoughtful deliberative decisions (Orasanu & Connolly, 1993). Instead, researchers (Cannon-Bowers & Salas, 1998; Kline, 1993) have found that choice in such settings often turns on rapid assessment of the situation followed by rapid selection of an action that "matches" the situational demands. These *recognition-primed* or *recognition-based* (RPD) models (Cohen & Freeman, 1997) emphasize thinking much less, and rapid matching much more, than do conventional decision models. Indeed, these expert performances, though often highly effective, may address phenomena rather different from what has conventionally been called decision making. Experts doing what they know how to do may use mental processes quite different from those used by others struggling to find a course of action when they do not know what to do. Effective expert performance may not rely on reflective decision processes of the conventional sort.

Theory of Signal Detection

An important model of decision making that has been largely ignored in JDM research is the Theory of Signal Detection (TSD). Its roots are in efforts to guide early radar operators in deciding whether or not a given display included a "signal" (e.g., a real target) hidden in the "noise" on the radar screen. The TSD approach is driven by practical prescriptive goals of improving decision making, and is only indirectly concerned with the psychology of the decision maker. The approach is, however, of great generality for many applied problems, from assessing cracks in aircraft wings to detection of breast cancer, and from evaluating job candidates to testing for AIDS, drug use, or lying.

TSD (Getty, Pickett, D'Orsi, & Swets, 1988; Swets, 1988) considers a diagnostic situation, one in which repetitive choices must be made between two alternatives. An evidence system of some kind produces probabilistic

information of imperfect accuracy to guide the choices. For example, a test for some specific disease might produce a numerical score: If the score is high, the patient is likely to have the disease; if it is low, he or she is unlikely to have it. What should you, the physician, do with a given score? Since the test is imperfect, there is a possibility of an error either way. If you act as though the disease is present when it is not (a false positive), you incur costs of wasteful, painful, and perhaps dangerous treatments and patient distress. If you act as though the disease is absent when it is actually present (false negative), you incur costs of failing to treat real disease. You need to set a threshold on the test score at which you will act. The threshold requires consideration of how likely the disease is to start with (the base rate), and the costs and benefits of the two different sorts of error you might make.

The evidence system offers the decision maker a set of choices, which can be summarized in a plot of false-positive probabilities versus true-positive probabilities, called an ROC curve (Figure 19.3). The decision maker may decide to set a very strict threshold, insisting on a very high test score so that the chance of a false positive is small. The price she pays is that she will miss many true positives. Alternatively she could choose a lax threshold, acting even when test scores were quite low. Doing this would push the true-positive probability higher, but only at the cost of more false alarms. The ROC curve is thus a summary of the evidence system's accuracy. A highly accurate system would offer very high true-positive probabilities with small false-positive probabilities. A completely useless system would offer identical probabilities of each. Anything that pushes the ROC up and to the left (higher true-positive probability

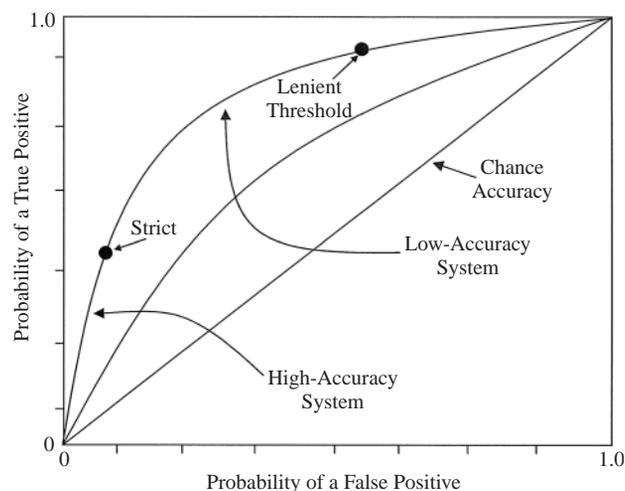

Figure 19.3 Diagnostic systems in TSD

for the same false-positive probabilities) represents an improvement in accuracy, and offers the decision maker a better range of options at which to set the threshold. Curve A thus offers a better menu of choices than does Curve B, and one research goal is to improve existing diagnostic systems in this way.

Independently of this improvement, it is possible to help the decision maker set appropriate thresholds, so as to make the best choice from those offered by the ROC curve. (Consider, for example, if you would want to use the same threshold on an HIV test for screening blood donations and for evaluating real patients. A false positive on the first case merely wastes a pint of good blood. In the second case, it would erroneously lead a patient to believe he had a life-threatening disease.) An excellent example of the TSD approach is Getty et al. (1988), in which the problem is improving the diagnosis of malignant breast cancers from mammograms.

Although it is easy to imagine the value of a TSD approach to a wide range of organizational decisions such as hiring, termination, new product development or R&D project selection, this potential does not appear to have been much tapped. [An exception is a report by Puranam, Powell, and Singh (2006) on due diligence procedures in corporate acquisitions.] Applications of TSD in organizations thus appear to be a promising research opportunity.

EMOTION AND DECISION MAKING

Visceral Emotions

Early research in decision making relied heavily on the “mind as a computer” model in which emotions were seen as irrelevant, or an active impediment, to rational choice. In the 1970’s and 1980’s Kahneman & Tversky’s (1979, 1984) more descriptive program showed how decision makers often use nonnormative heuristics rather than rational strategies, leading to systematic decision making biases. More recent research has started to explore the impact of emotions on decision-making processes.

Some of the earliest research in emotions and decision making investigated the impact of positive affect on cognition and information processing (Bower, 1981; Isen, Shalcker, Clark, & Karp, 1978; Loewenstein and Lerner, 2002). Many of these studies simply categorized emotions as either negative or positive, without further differentiation. Negative emotions were found to lead to pessimistic expectations and to more analytical processing of information, positive emotions to more optimistic expectations and increased use of heuristics (Forgas, 2003; Johnson &

Tversky, 1983; Mayer & Hanson, 1995; Schwarz & Clore, 1983). More recently, Slovic et al. (2007) proposed the affect heuristic in which the positive and negative affective features of options shape evaluations rather than weighing of pros and cons.

Increasingly, research is showing that different positive or negative emotions have distinct effects on decision making (Raghunathan & Pham, 1999). Cognitive-appraisal theories of emotion (Lazarus, 1991; Smith & Ellsworth, 1985) differentiate between how emotions are experienced and their subsequent effects. Smith and Ellsworth (1985) proposed a six-dimensional taxonomy in which emotions are described in terms of certainty, pleasantness, attentional activity, control, anticipated effort, and responsibility. Associated with each emotion is a core meaning (or core appraisal theme) which summarizes the specific harms or benefits that arise in the environment. Lazarus and Cohen-Charash (2001), for example, suggest that the core theme of fear is facing an uncertain threat. These core themes increase the likelihood of specific courses of action (i.e., action tendencies). Thus, fear motivates the person to avoid potential harm (Smith & Lazarus, 1990).

The Appraisal-Tendency Framework (ATF) was proposed by Lerner and Keltner (2000, 2001) to connect cognitive-appraisal theories to judgment and decision making. ATF assumes that emotions trigger changes in cognition, physiology, and action. These changes generally help individuals respond to the event evoking the emotion, but they often persist beyond the eliciting situation. These emotion-related processes (also called *appraisal tendencies*) guide subsequent behavior and cognition in goal-directed ways, even in response to objects or events unrelated to the original cause of the emotion (Gasper & Clore, 1998; Lerner, Goldberg & Tetlock, 1998).

It is important here to distinguish between integral and incidental emotions. Integral emotions are directly connected to the decision task and may have a normative basis for affecting the decisions made. Thus, considering the regret you may feel about the outcome of various decision options may affect how you make your decision (e.g., Connolly & Reb, 2003). However, incidental emotions have no normative relevance to the decision task at hand since they are the result of outside events. There is no justifiable reason why academic achievements are given more weight in college admission decisions on cloudy days (when moods are negative) than on sunny days (when moods are positive) (Simonsohn, 2007).

ATF has stimulated a number of studies of the carry-over effects on decision behavior of situationally induced

incidental emotions. Lerner and Keltner (2000, 2001) argued that two negative emotions, fear and anger, would have different impacts on risk assessment and risk-taking behavior. ATF proposes that fear involves appraisals of profound uncertainty: a sense that even basic needs are threatened by situational factors beyond one's control. By contrast, anger involves appraisals of certainty and individual control: A demeaning offense occurred with certainty and the situation is under the control of human agency. Consistent with these predictions, Lerner and Keltner (2001) demonstrated that angry people perceived a given situation as less risky than fearful people did. In an earlier study, Raghunathan and Pham (1999) showed that anxious (fearful) individuals preferred low-risk/low-reward gambles but sad individuals were more likely to select high-risk/high-reward gambles. Kugler, Connolly, and Ordóñez (2012) confirm previous findings that show fearful individuals are more risk averse than angry people when the source of the risk is a chance event, but the effect reverses when the risk comes from the uncertain choices of others. Other research has shown that disgust can eliminate the endowment effect (Lerner, Small, & Loewenstein, 2004), guilt can lead to more cooperative behavior (DeSteno et al., 2010), and envy increases the use of deception in negotiations (Moran & Schweitzer, 2008). Thus, results indicate that distinct emotions of the same valence may have predictably different impacts on decision making.

Emotions and decision making is becoming a hot research topic in JDM. Peters et al. (2006) describe four different roles that affect can have in judgment and choice: information, common currency, spotlight, and motivation. Affect as information (Schwarz & Clore, 2003; Slovic et al., 2002; Loewenstein et al., 2001) proposes that we consult our feelings when making our judgments and choices, using feelings as valid inputs to the process. Taking this a step further, affective responses to options can serve as the "common currency" in which they can be compared. Models focusing on cognitive appraisals and action propensities (Lazarus, 1991; Lerner & Keltner, 2000; Zeelenberg et al., 2008) portray emotions as motivators for behavior. Finally, affect can act as a spotlight by focusing our attention to particular attributes of a decision problem.

Cognitive Emotions

Regret, disappointment, and related emotions are by far the most-studied of the emotions associated with decision making. We focus here on psychological research,

noting that economic choice theorists such as Bell (1982, 1985), Loomes and Sugden (1982, 1986), Irons and Hepburn (2007), and Bleichrodt, Cillo, and Diecidue (2010) have used the same terms but apparently referring to rather different concepts (see Connolly & Butler, 2006). In contrast to the economic approach, psychological research on regret and disappointment takes seriously subjects' self-report measures of expected or actual emotional reactions to hypothetical scenarios (e.g., Connolly, Ordóñez & Coughlan, 1997; Gilovich & Medvec, 1994; Inman & Zeelenberg, 2002; Kahneman & Tversky, 1982) or actual events (Zeelenberg, Inman, & Pieters, 2001; Wroe, Turner, & Salkovskis, 2004).

In an early, much-cited study in this tradition Kahneman and Tversky (1982) gave subjects a brief scenario featuring two investors who each lose \$1,200 as a result of owning a certain stock, Stock A. One investor initially owned a different stock, Stock B, but switched to Stock A. The other considered Stock B but decided to hold onto his Stock A. Subjects were asked to predict which of the two would experience more regret at his loss. An astonishing 95% of subjects felt that the investor who switched would experience more regret. This was interpreted as evidence that unfortunate outcomes resulting from action are more regretted than identical outcomes resulting from inaction. This so-called action effect was thought to lead to an "omission bias" in which, for example, parents would be deterred from vaccinating their child because they would judge a bad outcome resulting from vaccination (an action) as worse than a similar bad outcome resulting from not vaccinating (inaction) (Ritov & Baron, 1990, 1992; Baron & Ritov, 1994). (See Connolly & Reb, 2002, for a detailed critique of these studies.)

Subsequent research painted a more complex pattern. Gilovich and Medvec (1994) showed that action-regret linkages could reverse over time. Seta, McElroy, and Seta (2001) found the two-investors effect reversed if the protagonists were described as entrepreneurial businessmen rather than ordinary risk-averse savers. Zeelenberg et al. (2002) asked participants how much regret a soccer coach would feel if his team lost after he either changed or did not change his team. The active coach was seen as more regretful than the inactive coach, but only if the team had previously enjoyed a winning record. If they had been losing, loss after *inaction* was regretted more. Inman and Zeelenberg (2002) compared consumers who either switched brands or stayed with a previously purchased brand and were dissatisfied with their purchase. Predicted regret after switching was lower if the consumer's prior experience with the initial brand had been poor, more

regrettable than if prior experience with the initial brand had been good.

Drawing on these and other studies, Connolly and Zeelenberg (2002) proposed Decision Justification Theory (DJT). DJT proposes that decision-related regret has two components, one associated with an assessment of the outcome ("outcome regret"), the other with the decision process that led to the alternative chosen ("process" or "self-blame" regret). Outcome regret is driven by comparison of the actual outcome with some reference point (sometimes the outcome of an unchosen alternative, sometimes other reference points such as the status quo, the expected outcome, or the outcome received by another person: see, for example, Connolly, Ordóñez & Coughlan, 1997; Ordóñez & Connolly, 2000). Process regret, in contrast, is driven by the individual's assessment of whether or not the decision was justified. For example, Zeelenberg et al.'s (2002) soccer coaches' decision to change a losing team is seen as justified (and thus not blameworthy or regrettable). Changing a winning team is unjustified, and more regrettable. Seta et al.'s (2001) entrepreneurial investors were justified in taking action, and poor outcomes thus less regrettable, because that is what entrepreneurs do. Inman and Zeelenberg's (2002) brand changers were justified in switching brands by their poor prior experience with the old brand. Reb and Connolly (2010) found that mothers whose vaccination decisions for their babies led to poor outcomes were expected to feel less regret when the decisions were based on a careful decision process. Indeed, although some justifications are specific to particular actions and roles (such as those of soccer coaches or entrepreneurs), the use of a careful, thoughtful, well-informed decision process—what Janis and Mann (1977) term a "vigilant" decision process—seems to be a regret-reducing justification across many contexts.

If poor outcomes are expected to be more regretted when they result from careless decisions, does the converse also hold? Does sensitizing people to possible regret motivate more careful decision processes? Recent evidence suggests that it does. Reb (2008) found that subjects primed to think about regret invested more effort, acquired more information, thought longer about their decisions, and made better final decisions than did those not so primed. Kugler, Connolly, and Kausel (2009) showed that regret priming can motivate more rational play in experimental games. Even quite subtle, unconscious priming of one or another type of regret can influence choice behavior. In a repeated decision task Reb and Connolly (2009) showed that unconscious priming of outcome regret led subjects to reject potentially painful feedback on the

outcomes of unchosen alternatives, impeding task learning and reducing final earnings (a trap they refer to as *myopic regret avoidance*). In contrast, subjects unconsciously primed for process regret accepted feedback (and thus the short-term pain of seeing that their outcomes could have been better), learned more, and performed better. Just as poor decision processes lead to increased regret, increasing the salience of possible regret can lead to improved decision processes.

Decision justification is central to Reason-Based Choice Effects (RBCEs; Shafir, Tversky & Simonson, 1993), such as the decoy effect (Huber, Payne & Puto, 1982), the accept/reject effect (Shafir, 1993), and the most-important-attribute effect (Slovic, 1975). In these RBCEs, “shallow but nice-sounding rationales” (Simonson, 1989, p. 170) can lead to nonnormative decisions. Recent work (Connolly, Reb & Kausel, 2010; Connolly & Reb, 2011) has shown that increasing regret salience can reduce or eliminate nonnormative decision RBCEs by prompting more scrupulous examination of one’s decision processes. Regret salience manipulations may thus constitute a relatively rare example of a theoretically grounded technique that effectively eliminates a class of decision biases and errors.

DECIDING: MULTIPLE RELATED EVENTS

Information Search, Information Purchase

One common way in which decisions are linked sequentially is when the outcomes of an earlier decision provide (part of) the information environment for the second. A doctor deciding on what laboratory tests to order for a patient is setting up the information environment in which she will make her subsequent diagnostic and treatment decisions. Similarly, a new product manager ordering a market survey is gathering information on which to base a later decision on whether or not to launch the product. In a shorter time frame, these acquisition and use processes merge.

Research on these processes has varied in how explicit is the cost of acquiring information. Russo and Doshier (1983) recorded the subject’s eye movements to study which items of information he or she extracts from a decision table and in what order. The “cost” of an information item is the cognitive effort involved in attending to an item. A related methodology is the information board (Payne, 1976), in which decision-relevant information is displayed to the subject in a matrix of small envelopes that may be removed and opened. A computer-based analog

called “Mouselab” has been extensively used (Payne et al., 1993) to explore underlying cognitive processes such as the combination rule being used by the subject.

Information cost is somewhat more explicit in work such as Wason (1960, 1968; Wason & Johnson-Laird, 1972) in which the subject makes an explicit request of the experimenter to turn over a card to decide whether or not an exemplar fits some unknown rule. In Wason and Johnson-Laird’s experiment, for example, subjects were shown four cards displaying E, K, 4, and 7. They were told that each card had a letter on one side and a number on the other and were asked which cards they would turn over to test the rule: “If a card has a vowel on one side, it has an even number on the other side.” Only 4% of their subjects selected E and 7, the correct choice. Almost half chose E and 4—an error, since the obverse of the 4 card cannot invalidate the rule, and thus produces, at best, evidence consistent with the rule but not testing it. This common finding has been interpreted as a general bias toward confirmatory search: seeking evidence that will confirm, rather than test, one’s initial beliefs. However, a penetrating analysis by Klayman and Ha (1987) suggests that such search patterns are better understood as examples of a “positive test” strategy, a generally appropriate heuristic that fails only in relatively rare situations, such as the four-card problem.

Explicit treatments of sampling cost flow easily from the Bayesian inference task discussed earlier (see the section on heuristics and biases). Instead of being presented with a sample of poker chips drawn from the selected bag, subjects are allowed to buy chips, at a fixed monetary cost per chip, before making their bet on which bag was selected, a bet for which they can win money. Findings from many such studies (see Einhorn & Hogarth, 1981, for a review) include:

- Partial sensitivity to normatively relevant variables. For example, Pitz (1968) found increased buying when cost per chip was reduced and diagnosticity was increased. Snapper and Peterson (1971) found some sensitivity to variations in information quality.
- Sensitivity to normatively irrelevant variables, such as information order (Fried & Peterson, 1969) and total information available (Levine, Samet, & Brahlek, 1975).
- Substantial losses (e.g., Kleiter & Wimmer, 1974), which persist with little or no learning over repeated trials (e.g., Wallsten, 1968).
- Both overpurchase and underpurchase (e.g., Hershman & Levine, 1970).

Largely parallel results are reported in an alternative, regression-based model of information purchase by Connolly and colleagues (see Connolly, 1988, for an overview).

The evidence from both Bayesian and regression models of information purchase suggest that subjects routinely and persistently make costly errors in balancing the costs and benefits of their information purchases. This should not be surprising. Optimal information purchase requires the subject to make accurate assessments of how accurate the different sources are, to select the best subset, and to combine the information acquired in an optimal way. Extensive evidence suggests that all three subtasks are quite difficult. It is thus likely that serious nonoptimalities will be found when the balance must be struck in practical settings. This is consistent with the reluctance of patients to seek second and third medical opinions before undertaking major courses of treatment, which, in our terms, represents a major underpurchase of decision-relevant information. It is also consistent with the huge body of evidence (Guion, 1975) on the predictive uselessness of unstructured job interviews—which are, nonetheless, still very widely used, and represent a huge overpurchase of decision-irrelevant information. Wherever information costs and benefits need to be brought into balance, then, there is good reason to suspect significant departures from optimality (March & Feldman, 1981). Applications range from improved design of Web sites (e.g. Peterson & Merino, 2003) to the impact of cell-phone use on drivers' visual search patterns (Recarte & Nunes, 2003).

Sunk Costs and Escalation of Commitment

One important way in which a series of decisions over time can be linked is when nonrecoverable costs incurred at an earlier stage influence decisions at a later stage. The prescriptive advice on such matters is clear: The costs are “sunk,” and should play no part in the later decisions. Equally clearly, many of us violate such advice. We finish indifferent restaurant meals, sit to the end of bad movies, and remain in failed relationships so as not to “waste” the money spent on the restaurant bill or movie ticket or the time “invested” in the relationship. We fall, in short, into the “sunk-cost trap.”

Arkes and Blumer (1985) report 10 small experiments in which sunk-cost effects were demonstrated. Though most used a scenario format (and are thus open to the criticism that they involved the subjects in no real decisions), Experiment 2 made clever use of actual theater-ticket buying decisions to investigate sunk-cost effects. Of patrons

buying season tickets for a local theater, one third paid full price, one third were given a modest discount, and one third a substantial discount, from the normal price. Patrons paying full price subsequently attended significantly more of the performances than did those who received discounts, though the effect faded later in the theater season. Arkes and Blumer interpret this as evidence that the larger sunk costs incurred by the full-price patrons influenced their later attendance decisions.

Similar effects have been reported in organizational (e.g., Staw & Ross, 1989) and other contexts (Brockner, Shaw, & Rubin, 1979). In a typical organizational study, Staw, Barsade, and Koput (1997) found that loan officers at banks were more likely to continue funding and extending problem loans when they had been responsible for the initial lending decision than when they took over responsibility for the loan after its initiation. A related effect in the persuasion literature, the “foot in the door” technique, involves winning compliance to a large request by first obtaining compliance to a smaller one (Freedman & Fraser, 1966). More subjects agreed to put up a large lawn sign when they had earlier been asked to sign a petition on the same subject than when subjects were approached directly with the large request.

Despite such apparently robust demonstrations, there is some confusion as to what phenomena are appropriately included in “sunk-cost effects,” and an embarrassing range of partially conflicting explanations has been offered. One setting in which escalating commitment has been demonstrated in scenario studies is in continuing to fund partially completed projects (e.g. Staw, 1976). However, when degree of project completion and expenditure are independently manipulated (Conlon & Garland, 1993; Garland, 1990), only the former factor shows an effect. Moon (2001) found that the two effects can operate independently of one another, and He and Mittal (2007) found that their relative impact changed over the course of a project. Public use of sunk-cost arguments by public officials may reflect either the entrapment of the speaker or the calculation that sunk-cost arguments will persuade the audience. Staw and Hoang (1995) claim to have demonstrated sunk-cost effects in their finding that basketball players drafted early (and expensively) into the NBA thereafter are played more and traded at higher prices than their performance appears to justify. The result could, however, simply reflect the failure of the authors' performance model to capture just what a player is worth to a team. It is thus somewhat unclear just what is to be included as a sunk-cost effect, or how reliably such effects can be reproduced.

One account of the sunk-cost effect has been offered in terms of Prospect Theory's loss function. The initial cost is taken as a loss (below the reference point), thus putting the decision maker into a region of risk seeking. Continuing the project now offers a risky project with some hope of gain, while abandonment forces acceptance of a certain loss (Thaler, 1980). Arkes (1996) and Arkes and Ayton (1999) argue instead for a quite general aversion to "waste," a category mistakenly expanded to include partially completed projects or previously incurred costs. Staw (1976) and Aronson (1984) offer accounts based on self-justification, while Kiesler (1971) sees behavioral commitment as the central mechanism. Ku (2008) and Wong and Kwong (2007) tie escalation to decision-related regret, and Higgins (2002) offers an account based on his prevention/promotion framework. Brockner (1992) presents a multitheoretical perspective.

Overall, then, the sunk-cost effect and its relatives seem obviously worrying, possibly widespread, and open to a broad range of theoretical accounts. There is, however, a suggestion that we may be lumping together several rather different effects, each driven by a complex psychology of its own.

Dynamic Decision Making

Dynamic decision problems are those in which the decision maker may act repeatedly on an environment that responds to his or her actions and also changes independently over time, both endogenously and exogenously (Edwards, 1962). An example might be a senior manager's efforts to improve low morale in an organization. She may, over a period of months, try a number of different interventions, scaling up successes and abandoning failures. Over the same period various factors internal and external to the organization may also affect morale. Clearly, such problems set decision makers extraordinary challenges.

They have also proved difficult for researchers, partly because of their inherent complexity, partly because of the experimenter's partial lack of control. Complexity implies difficulty in deriving optimal strategies. Lack of control arises from the fact that the problem facing the decision maker at time t is partially the consequence of his or her earlier decisions, as well as of the experimental conditions imposed. On the positive side, the growing availability of computers has helped both in the creation of realistically complex experimental environments and in the analysis of strategic alternatives. Some examples of the sorts of studies this allows include:

- *Simulated medical diagnosis:* Kleinmuntz and Kleinmuntz (1981) created a diagnostic task in which simulated doctors attempted to treat simulated patients on the basis of their initial symptoms and of the results of any tests the doctor chose to order. They could also act at any point to administer "treatments" which might or might not improve the patient's health. Health fluctuated, over the 60 time periods of each trial, both in response to the doctor's interventions and to the preset (downward) course of the disease. The simulated strategies explored included Bayesian revision, a heuristic hypothesis-testing strategy, and a simple trial-and-error approach. The computationally intensive Bayesian strategy yielded only modest improvements over the heuristic strategy in this environment, and even the simplistic trial-and-error approach did well on some cases. Further simulation results are reported in Kleinmuntz (1985), and experimental results with real subjects in Kleinmuntz and Thomas (1987).
- *Artificial worlds:* A number of European researchers (see Mahon, 2000, for a review) have explored dynamic decision problems with the aid of simulated worlds: firefighting in simulated forests (Brehmer, 1990), economic development in a simulated third-world country (Reither, 1981), control of a simulated smallpox epidemic (Hesse, 1982), and so on. Funke (1995) provides an extensive review, with studies classified as to the person, task, and systems factors each examined. Typical findings are those of Brehmer (1990) from his simulated firefighting task. Subjects initially perform quite poorly, but can learn this complex task with repeated play. Feedback delays impede learning substantially. Opportunities to offset feedback delay by decentralizing decision making were mainly ignored.
- *Systems dynamics:* A group strongly associated with MIT (Diehl & Sterman, 1993; Paich & Sterman, 1993; Sterman, 1987, 1989) base their dynamic decision making tasks on feedback dynamics models in which coupled feedback processes make response over time extremely nonintuitive to most subjects. For example, in Sterman (1987) subjects faced a capital budgeting task in which there was significant lag between ordering new equipment and having it available to meet increased demand. Most subjects in this task generated very large and costly oscillations, despite instruction in system linkages.

As this sampling suggests, empirical studies of dynamic decision tasks are difficult. The tasks themselves

are quite complex, even if greatly oversimplified versions of real-world analogs. Amateur subjects are thus easily overwhelmed, while expert subjects object to the unreality of the tasks. Findings thus tend to be task-specific and difficult to aggregate over different studies. Progress, clearly, is being made, but there are important challenges in this area.

MULTIPLE DECISION MAKERS

Organizations make many important decisions in groups, partly because the complexity of the issues requires multiple perspectives, partly because multiple areas of the organization want influence. (Organizational researchers commonly distinguish between *groups* and *teams*, but decision researchers refer to both as *group decision making*, a usage we will follow here). Group decisions may potentially improve decision quality, but at the cost of significantly more complex decision processes: Information must be shared, beliefs and preferences combined, and social interaction, conflict, and cooperation actively managed. In this section, we examine research addressing these issues for certain and uncertain outcomes, technology designed to aid group decision making, and negotiation between two parties.

Group Decision Making

Groups must communicate information if they are to improve decision quality. Thompson (2011) notes several possible impediments to information flow in teams: (a) message tuning in which the sender gives more or less information based on what she believes the receiver needs; (b) the sender lacks proper perspective taking and assumes the receivers know something that they do not (curse of knowledge), and (c) sender believes that other teammates know and understand their thoughts and attitudes (transparency illusion). Social factors also affect the group's behavior. Senders may distort messages so as to be better received by the receiver, or use indirect speech (e.g., "The new VP of sales has an interesting strategy" vs. "I think the VP of sales is making some tactical errors") to show deference to superiors.

Information flow is further degraded when a few team members do a disproportionate amount of the talking, known as the uneven communication problem (Shaw, 1981). Members may also display the common information effect (Gigone & Hastie, 1997), discussing only information they hold in common. In hidden profile tasks

(Stasser, 1988), the best option can be overlooked unless members' unique information is revealed. One remedial method is to require members to rank order the options rather than merely state their top choice (Hollingshead, 1996), which allows options with unique positive information to stay in the consideration set rather than being selected out early in the process. Hastie and Kameda (2005) tested nine different rules for combining member preferences over multiple options. Computationally intensive rank-ordering methods (such as Borda and Condorcet) performed very well, but simpler majority/plurality rules also performed surprisingly well. However, these rules are vulnerable to the hidden profile problem noted above.

Are groups better or worse decision makers than individuals? The answer depends on the situation and decision to be made (and, of course, on the criteria for "good." In many settings a technically inferior decision to which the whole group as agreed may be an excellent choice.). There is no clear pattern of groups either reducing or increasing decision biases. Hindsight bias was slightly reduced with groups compared to individuals (Stahlberg, Eller, Maass, & Frey, 1995), though Bukszar and Connolly (1988) found no effect. Groups were even more affected than individuals by the representativeness heuristic in a base-rate (cab) problem (Argote, Seabright, & Dyer, 1986). And groups, like individuals, appear to be biased in their information search (Schulz-Hardt et al., 2000). Tindale (1993) argues that group effectiveness depends on the demonstrability of the problem. If one solution can be unambiguously demonstrated to be the correct answer, then the group will usually adopt it. Otherwise (as in the cab problem), the group decides by majority rule and individual errors are maintained (Tindale & Davis, 1985). Tindale (1993) presents data in which decision biases are reduced or enhanced by groups as compared to individuals. Groups may tend to be more overconfident than individuals (Fischhoff, Slovic, Lichtenstein, 1977). They may also be more economically rational, offering less than individuals in the ultimatum game and exiting more quickly in a centipede game (and, interestingly, earning less while doing so) (Bornstein, Kugler, & Ziegelmeyer, 2004; Bornstein & Yaniv, 1998). Cooper and Kagel (2005) compared two-person teams to individuals in a signaling game and found that teams were more strategic, had higher outcomes, and transferred knowledge better in response to changes in payoffs.

Kerr, MacCoun, and Kramer (1996) reviewed studies of decision biases at both individual and group levels. They also conclude that decision biases can be either

smaller, equal to, or higher for groups as compared to individuals depending on the type of decision, the initial values of the individuals, and how individual values are aggregated into group decisions. They propose a formal model of group decision making, the Social Decision Scheme model (Davis, 1973; see the special issue of *Organizational Behavior and Human Decision Processes*, 1999, on this topic). This model links the aggregation rule for individual values and the decision rule used (e.g., “majority wins,” “truth wins,” or “all options equiprobable”) to the outcome selected. For example, Whyte and Sebenius (1997) found that groups did not debias individual estimates, which were improperly anchored on inappropriate anchors. Using symmetric differences squared (SDS) methodology, the authors showed that group estimates were based on the majority view that was biased before group discussion began. Finally, Yaniv (2011) showed that framing effects were eliminated in groups if the members were heterogeneous with respect to initial frame but were polarized if they all were exposed to the same frame before meeting as a group.

There are some conditions in which groups generally improve decision quality. Several studies indicate that heterogeneity (of attributes such as personalities, gender, attitudes, and experience) is positively related to creativity and decision effectiveness (Jackson, May, & Whitney, 1995). Guzzo and Waters (1982) found that the quality of group decisions and the number of diverse alternatives increased when expression of emotion was delayed until after alternative solutions were discussed. They suggest that early expression of emotions may reduce the group energy and narrow the range of accepted ideas. Under time pressure, quality of decisions generally declines, though task cohesion can help offset this effect (Zaccaro, Gualtieri, & Minionis, 1995). Finally, the popular book *The Wisdom of Crowds* (Surowiecki, 2004) provides anecdotal evidence that large numbers of people (crowdsourcing) can outpredict experts if individual opinions are diverse and independent; decentralized so that individuals can specialize and draw upon their local knowledge; and a method is provided for aggregating the individual judgments. However, Kostakos (2009) examined three popular voting Web sites including Amazon.com and found that the “crowd” typically includes a small group of experts that do the majority of the ratings. The wisdom of crowds may thus be heavily derived from the wisdom of a few experts.

Groups can also degrade decision performance. Janis (1972) coined the term *groupthink* to label “a mode of thinking that people engage in when they are deeply

involved in a cohesive in-group, when the members’ strivings for unanimity override their motivation to realistically appraise alternative courses of action.” A classic example is the failed Bay of Pigs invasion in which the American military sent Cuban exiles to overthrow the dictator Castro. These groupthink decisions are characterized by highly cohesive groups under high stress from an external threat and suffering low self-esteem from earlier failure or decision difficulty. Other attributes may also contribute: an illusion of invulnerability, collective rationalization, belief in the inherent morality of the group, insulation, lack of impartial leadership, direct pressure on dissenters, stereotypes of out-groups, and lack of established decision-making procedures. However, note that merely increasing group familiarity is not sufficient to cause groupthink: Watson, Michaelsen, and Sharp (1991) found that groups who spent more than 30 hours on decision-making tasks were more effective than individual decision makers.

Group Decision Support Systems (GDSSs)

Group decision support systems are designed to facilitate group decision making. GDSSs usually take the form of computerized, networked systems that aid in idea generation and decision making. A brief summary of key findings follows; a more detailed account can be found in Hollingshead and McGrath (1995).

In general, groups using GDSS demonstrate more equal participation and increased focus on the task than unaided groups but also interact less, take longer, have lower overall consensus, and report less satisfaction with the process and decision (Hollingshead & McGrath, 1995; McLeod, 1992). GDSSs provide a unique environment in which group members can interact anonymously. Jessup, Connolly, and Tansik (1990) showed that anonymous members using GDSSs tended to be more critical, more probing, and more likely to generate comments or ideas than when individual contributions were identified. For a very recent summary of past findings and future prospects for GDSSs, see Gray, Johansen, Nunamaker, Rodman, and Wagner (2011).

Do face-to-face (F2F) or GDSS groups make better decisions? The answer depends on the task. As indicated previously, GDSSs are better for idea generation. However, F2F interactions appear to be superior for problem solving and conflict resolution. Interestingly, Hollingshead and McGrath (1995) suggest that some of the benefits of GDSSs may stem from the structured aspects of the decision-making process rather than the GDSS itself. Shirani (2006) found that GDSS groups were more likely to

share unique information (i.e., to avoid the common information effect) than F2F groups. Archer (1990) found no differences in decision quality between GDSS and F2F when the decision process phases of a complex business situation were organized and managed in a rational manner.

Research on the behavioral impacts of GDSSs on group decision performance is still in the early stages and has largely used ad-hoc student teams. Research needs to be done on intact groups that have had experience working and making decisions together. In addition, as noted above, it may be that simply structuring the decision-making task can improve performance. However other features that GDSSs can provide may improve decision making in ways that cannot be achieved without them. A recent survey (Shim et al., 2002) indicates that organizations are increasingly making decisions in globally dispersed groups necessitating computer-mediated communication systems (CMCSs) and GDSS. This review indicates that F2F interaction is richer than CMCS and leads to many positive outcomes such as increased group cohesion, enhanced creativity and motivation, increased morale, fewer process losses, and better decisions. Given that organizations are increasingly using virtual teams that must interact entirely with CMCS, care must be taken to “foster interaction, inclusion and participation, which are all related to the feeling of ‘being there’ or social presence” (Shim et al., 2002). There is some evidence that virtual teams are less prone to escalation of commitment in a new product development context (Schmidt, Montoya-Weiss, & Massey, 2001), suggesting that there are contexts in which the lack of social richness can be valuable to group decision making. However, organizations should be cautious. Results of a meta-analysis (Baltes, Dickson, Sherman, Bauer, and Laganke, 2002) indicate that use of CMCSs decreases group effectiveness, increases time required to complete tasks, and decreases member satisfaction compared to F2F groups.

Negotiation

Negotiation is the process in which people determine “what each side shall give and take or perform and receive in a transaction between them” (Thompson, 1990). There is a vast literature in the field of negotiation and our review here is highly cursory. For further information on the psychological aspects of the negotiation process, see Thompson, Wang, and Gunia (2010), Bazerman, Curhan, Moore, and Valley (2000), and Tsay and Bazerman (2009). We will focus on dyadic negotiations; however, there

is also an extensive literature in multiparty negotiations and coalition formations that we do not discuss here (see Crump & Susskind, 2008, and Murnighan, 1986, for reviews).

Early social psychological work in the 1960s and 1970s focused primarily on individual differences or situational characteristics. The extensive literature on individual differences has shown little effect on negotiations (Thompson, 1990). More recently, researchers have examined the interaction between individual differences and contextual variables. For example, Kray, Thompson, and Galinsky (2001) examine how men and women adopt different bargaining strategies after stereotypes about effective negotiators are activated. When stereotypes are activated implicitly, men are more assertive than women and men prevail in a distributive negotiation. However, women are more assertive (and more successful negotiators) than men when stereotypes are activated explicitly. In addition, other research (Babcock, Gelfand, Small, Stayn, 2006; Small, Gelfand, Babcock, & Gettman, 2007) indicates that women are less likely to initiate negotiations, but perform on par with male counterparts when they do.

The 1980s through 1990s used the behavioral decision research (BDR) as a framework. Raiffa (1982), in his decision analytic approach, shifted the attention away from prescriptions of optimal strategies to descriptions of actual negotiation behavior. Rather than propose optimal bargaining solutions based on objective facts of a negotiation, this type of research examines the perceptions of the situation, the other party, and the self. Thus, this format was not to present a normative picture of negotiations but to describe behavior and, at times, demonstrate the systematic deviations from the rational negotiator. In the 1990s, a social cognitive perspective was developed, with the focus on the negotiator as information processor (Thompson, Peterson, & Kray, 1995).

Many of the findings in this field have taken the heuristics and biases results (such as framing and overconfidence) and found them in a negotiation context. A great deal of evidence indicates that the framing of a negotiation has strong implications for negotiations. For example, in a labor–management salary negotiation (Bazerman, 1984), a raise from \$10 to \$11 an hour can be seen by labor as a gain of \$1 or as a loss of \$1 if the union demanded \$12 an hour. Likewise, management can view \$11/hr as a loss of \$1, compared to the previous salary, or as a gain of \$1, compared to the union’s demands. The greater impact of losses over equal-magnitude gains (i.e., “loss aversion”) results in a reluctance to trade concessions (Ross & Stillinger, 1991), creating a barrier to conflict

resolution. Neale and Bazerman (1985) showed that negotiators with positive frames were more likely to make concessions and were more successful than those with negative frames (however, negatively framed negotiators earned on average more per transaction when an agreement was reached). Real estate agents have been shown to anchor on the list price of a house and insufficiently adjust when assessing the value of a home (Northcraft & Neale, 1987), conflict management experts fall prey to the availability bias and do not search sufficiently for necessary information (Pinkley, Griffith, & Northcraft, 1995), and student negotiators were overconfident in believing their offer will be accepted in final arbitration (Bazerman & Neale, 1982).

Additional biases have been found that are unique to the negotiation context. One well-known bias, the fixed-pie assumption, occurs because the negotiators assume that they must distribute a fixed-pie (Bazerman, Magliozzi, Neale, 1985) rather than searching for integrated solutions that increase joint payoffs. This belief in the mythical fixed pie can also lead to the incompatibility bias (Thompson & Hastie, 1990, Thompson & Hrebec, 1996), in which negotiators falsely assume that their interests are incompatible with those of their opponents. Bazerman (1998) gives an example of a labor–management negotiation in which both sides value increased training programs, and thus, the work force would be more flexible for management and lead to more job security for labor. However, due to the incompatibility bias, they settle for a less than optimal arrangement because they do not realize that they have common interests and negotiate as if a compromise must be reached. In addition, the fixed-pie assumption can lead to devaluing any concession made by the opponent (Ross & Stillinger, 1991): If management is offering more job training, it must not be too costly, or it must be benefiting them in some way.

Recent research augments the BDR perspective with a more cognitive focus (Thompson et al., 2010) that integrates subjective values of outcomes other than the negotiated agreement (Curhan, Elfenbein, & Xu, 2006) such as the relationship with the negotiating partner. For a recent review of the negotiation area see Thompson et al. (2010) for a general overview and Tsay and Bazerman (2009) for a decision-making perspective. One area that has received a great deal of attention recently is the impact of affect on negotiations (see Druckman & Olekalns in the 2008 special issue on emotions in negotiation). This can be further divided into emotions resulting from the negotiated outcomes (Galinsky, Seiden, Kim, & Medvec, 2002; O'Connor & Arnold, 2001), emotions spilling over from other events (Wood & Schweitzer, 2010), displayed

emotions (Sinaceur & Tiedens, 2006), and the anticipated emotions of the opponent (Van Kleef, De Dreu, & Manstead, 2004).

CONCLUDING COMMENTS

As this selective survey of JDM connections to I-O psychology has, we hope, made clear, we see the linkage between the two fields as having accomplished significant work, but as having a potential for much more. As Highhouse (2002) points out, there are many topics in I-O that seem to fall naturally into the JDM domain: personnel selection and placement, job choice, performance assessment, feedback provision and acceptance, compensation, resource planning, strategic forecasting, and others. The two disciplines have, however, remained largely isolated, despite the clear potential for collaboration. Our hope is that the present chapter may contribute something to stimulating this linkage.

It may help a little if we clarify what we see as the current state of development of JDM. The mere name of the discipline makes an implicit claim: that there is sufficient commonality across different decision situations for a general theory of decisions to make some sense. We would assess the evidence to date on this point as mixed. Weather forecasters do have *something* to say to heart surgeons, and hog judges have *something* to say to HR practitioners; but it would be absurd to claim that we have a successful general theory of judgment and decision that embraces all four territories as mere applications. Any general claims require extensive local tinkering before they bring much insight to specific practical applications.

In our view the best contribution JDM can currently make to I-O issues is as a fertile source of interesting hypotheses, and as a provider of frameworks and instruments. For example, we would not read the literature on overconfidence in lab problems as supporting strong predictions that managers will be overconfident in predicting hiring needs. It does, we think, make such a hypothesis worth exploring. It also suggests how the relevant research could be conducted. In return, such research would inform JDM of the boundary conditions on its findings: When, for example, does overconfidence generalize, when is it bounded, what mechanisms are successful in minimizing it? It is this two-way enrichment of one another's disciplines that we see as the potential for an enhanced collaboration between JDM and I-O. Our fond hope is that this chapter may do something to facilitate the interchange.

OUTCOMES OF WORK DESIGN	544	REFERENCES	553
WORK REDESIGN INTERVENTIONS	546		

In the late 1990s, when the first version of this chapter was written, we sought to comprehensively review past work design research with an eye toward identifying potentially fruitful areas of future research (Morgeson & Campion, 2003). Our intent was to try and stimulate interest in work design research. At that point, despite having had an enormous impact on organizational success and individual well-being, research on the topic appeared to be waning in industrial–organizational (I-O) psychology circles (Campion, 1996). As highlighted by Humphrey, Nahrgang, and Morgeson (2007), starting in the late 1980s work design publications in top-tier journals significantly declined. Since the publication of our chapter, however, the field seems to have rediscovered work design research. This is exemplified by a number of review and conceptual articles on work design (Grant, 2007; Grant & Parker, 2009; Morgeson & Humphrey, 2008; Parker & Ohly, 2008), a meta-analysis of hundreds of studies (Humphrey et al., 2007), a meaningful increase in the number of top-tier academic journal publications on the topic, and a *Journal of Organizational Behavior* special issue dedicated to work design research (Grant, Fried, Parker, & Frese, 2010). We are thrilled about this renewed interest in work design and any potential role our chapter may have played in helping reenergize research in this area. The goal of the present chapter is to update our previous chapter by incorporating some of the most recent contributions made in the field of work design.

Work design continues to be an essential area of research for several reasons. First, it resides at the intersection of I-O psychology and thus represents an important

synthesis between these two domains. Because work design theory draws heavily from motivational theories in organizational psychology and incorporates such central industrial psychology topics as the analysis of jobs and their requirements, it is fundamentally integrative in nature. Second, work design has great practical significance to organizations as they try to attain such diverse outcomes as efficiency and satisfaction. Because a major part of every manager’s job involves the design of a subordinate’s work, it is an area that has considerable practical implications. Finally, the nature of work has a profound influence on those performing it, and attention to the design aspects of work can yield insight into individual outcomes. This is an area of research where there are clear and meaningful individual, organizational, and societal implications. Thus, it is not surprising that work design is once again a vibrant area of research.

We took on the revision of this chapter with the goal of providing readers with the latest developments in work design research and offering a comprehensive review of the work design literature. Our focus is primarily on the content and structure of jobs individuals perform and the broader context within which work is performed. This broadened focus on work design not only enables us to capture the range of research conducted under the auspices of job design, but also allows us to expand our focus somewhat to incorporate research that extends beyond what has traditionally been studied in the domain. We will concentrate primarily on research that has appeared in the I-O and organizational behavior literatures (because of space constraints), but readers should recognize that

a number of different disciplines have also investigated work design issues (e.g., industrial engineering, operations management, ergonomics).

In keeping with the structure of the earlier chapter, we use the integrated work design framework (Figure 20.1) as a guide. This framework has been slightly updated to reflect recent progress made (Morgeson & Humphrey, 2008). We begin the chapter with a review of the major work design perspectives that have been investigated in I-O psychology and organizational behavior realms. This serves as the basis for the remaining sections, outlining the history of work design research and its theoretical underpinnings. We then consider the variety of contextual influences on work, including social and structural factors. Next, we examine characteristics of work that have been identified in the literature. This includes questions about the structure of work, whether incumbent self-reports of work characteristics reflect objective properties of the job or subjective perceptions, and potential measurement concerns.

Based on current work design research, we identify a range of mediating mechanisms assumed to underlie work design effects. This helps explain how work design influences outcomes. We then examine the empirical relationships between work design features and attitudinal, behavioral, cognitive, and well-being outcomes. We discuss how work redesign impacts outcomes and consider the evidence for individual differences in work design. Finally, we conclude the chapter with a discussion of the updated work design framework provided in Figure 20.1 and identify several trends that are likely to influence work design in the future.

MAJOR WORK DESIGN PERSPECTIVES

This section introduces the major perspectives on work design. Critical evaluation of these approaches will be presented in subsequent sections where the major issues in work design research are reviewed.

Scientific Management

The works of Smith (1776) and Babbage (1835) serve as the foundation for contemporary work design theory. These theorists discussed how the division of labor could increase worker efficiency and productivity. They noted that breaking work into discrete jobs enables specialization and simplification, allowing workers to become highly skilled and efficient at performing particular tasks.

Additional efficiency gains occur because: (a) workers do not switch between tasks as much; (b) distractions are reduced due to fewer work elements; and (c) workers recognize a variety of small ways to further increase efficiency.

The first systematic attempt documented in the literature to design jobs utilizing these principles occurred in the early part of the twentieth century through the efforts of Taylor (1911) and Gilbreth (1911). Dubbed “Scientific Management” by Taylor (1911), these efficiency-oriented approaches focused on principles such as specialization and simplification as a means of easing staffing difficulties and lowering training requirements. Critical to these approaches is the notion that management should decide how to divide and design work, and then institute control mechanisms (e.g., training, incentive systems, supervision) to ensure work is completed in accordance with management’s wishes. Although the problems associated with scientific management have been well documented, many of its principles still underlie modern work design (Cherns, 1978; Wall & Martin, 1987).

Job Enrichment Approaches

One of the problems with designing work to maximize efficiency is that it commonly ends up being repetitive, tedious, and boring. Partly as a reaction to the reductionistic nature of efficiency-oriented work design, and partly as an acknowledgment of human potential and higher-order needs, organizational theorists began to focus on the characteristics that could enhance worker satisfaction and provide for intrinsic needs (e.g., Herzberg, Mausner, & Snyderman, 1959; Likert, 1961; McGregor, 1960). Two primary theoretical models have been developed under the auspices of job enrichment: Herzberg’s Motivator-Hygiene Theory and Hackman and Oldham’s Job Characteristics Theory.

Motivator-Hygiene Theory

Motivator-Hygiene Theory (Herzberg et al., 1959) codified how work could serve to motivate employee behavior. In brief, this theory distinguished between aspects of work that are satisfying and motivating (“motivators”) and those that are dissatisfying (“hygiene factors”). Such things as recognition, achievement, and advancement are intrinsic to the work and were termed motivators. Such things as salary, company policies, and working conditions are external to the work itself and were considered to be hygiene factors. According to Motivator-Hygiene Theory, only job changes that impact motivators will improve

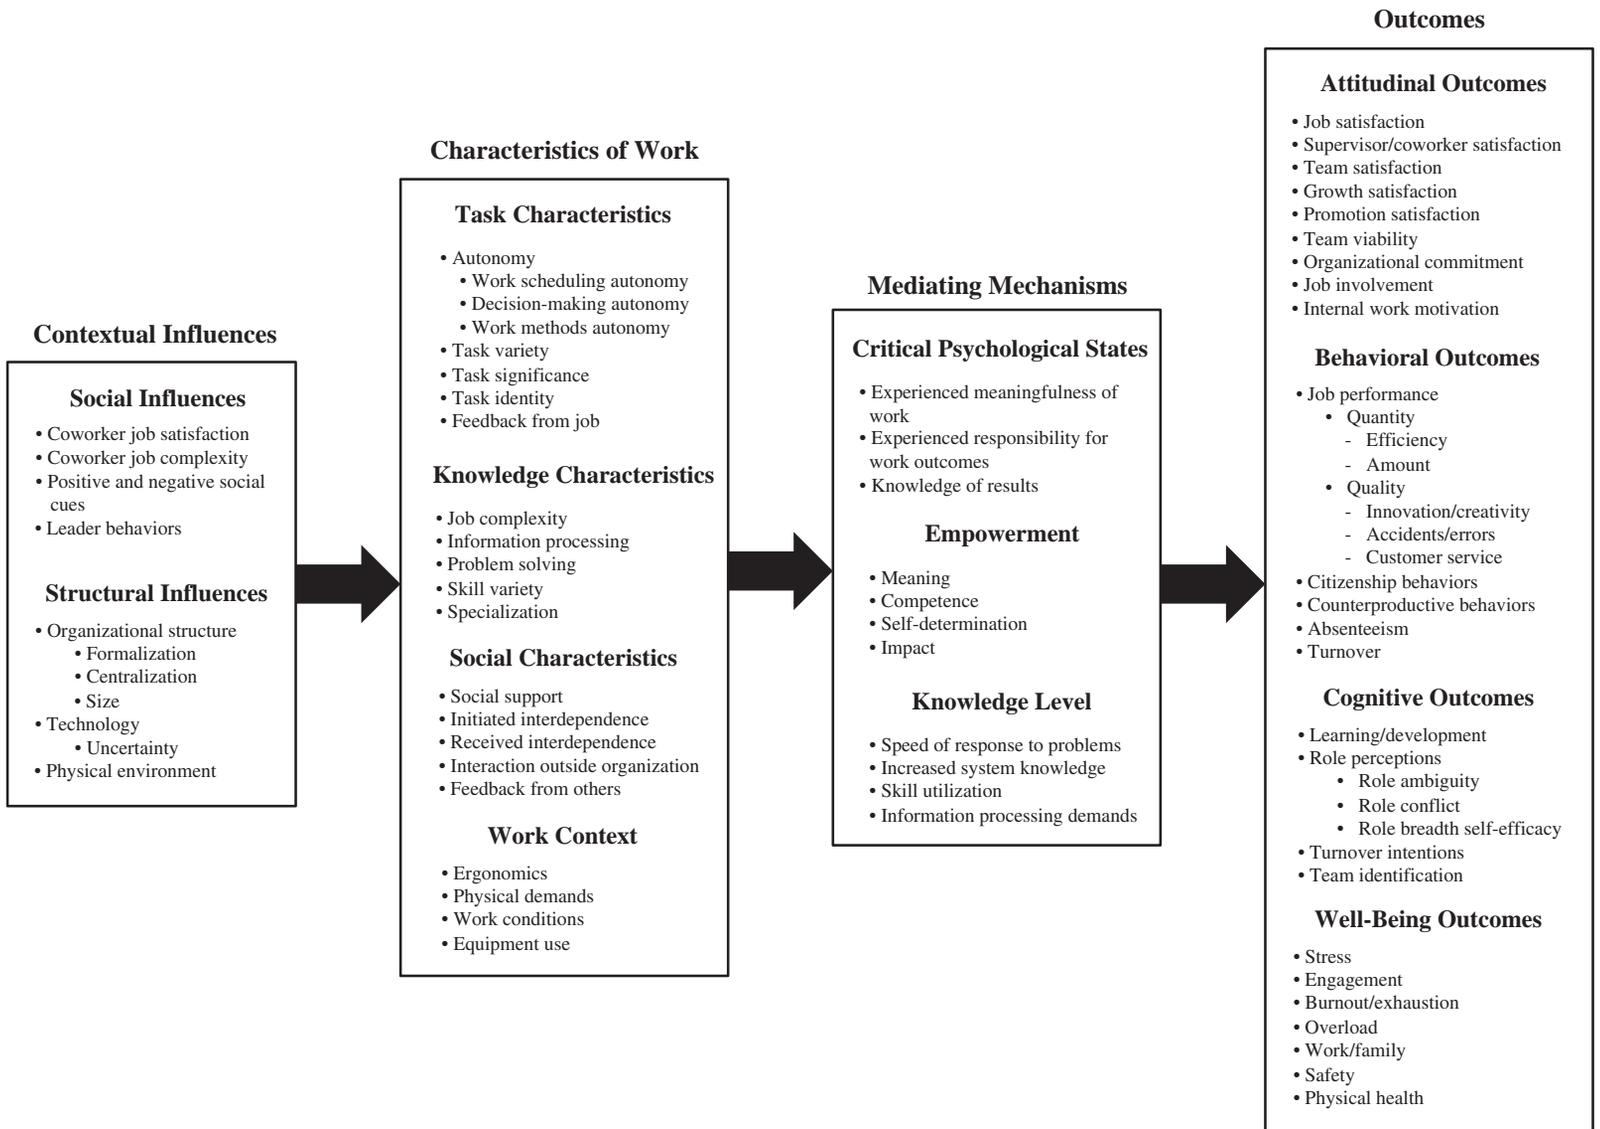

Figure 20.1 Integrated work design framework

satisfaction and motivation. Changes aimed at hygiene factors will reduce dissatisfaction, but will not affect satisfaction or motivation. Although research generally failed to confirm this and other key aspects of this theory (Locke & Henne, 1986), it remains important because it represents an early attempt to understand how the content of work can impact worker motivation and marks the beginning of interest in job enrichment.

Job Characteristics Theory

Although Motivator-Hygiene Theory stimulated research and served as the foundation for a number of work redesign efforts (Herzberg, 1976), it was beset by a number of significant weaknesses (Oldham, 1996). Research by Turner and Lawrence (1965) and Hackman and Lawler (1971) sought to address these weaknesses and understand how job characteristics relate to individual reactions to work. This research directly led to the job characteristics theory, most fully articulated by Hackman and Oldham (1975, 1976, 1980).

The job characteristics approach suggested that five job characteristics produce critical psychological states in the job holder, which ultimately results in a set of positive work outcomes. First, skill variety involves the use of a wide variety of the worker's skills and abilities. Second, task identity involves the extent to which the worker feels he or she is responsible for a meaningful and whole part of the work. Third, task significance involves the impact the job has on the lives of others. Together, these three job characteristics are presumed to increase the meaningfulness of work.

Fourth, autonomy involves the amount of freedom and independence an individual has in terms of carrying out his or her work assignment. This was expected to increase experienced responsibility for work outcomes. Fifth, feedback concerns the extent to which the job duties provide knowledge of the results of the job incumbent's actions. This was expected to provide knowledge concerning the results of work activities. It is important to note that this explicitly refers to feedback obtained directly from the job itself. This differs, however, from the manner in which Hackman and Lawler (1971) conceptualized feedback. They posit that feedback may come from the task itself, or it may come from supervisors or coworkers. This difference becomes important later when we discuss the social environment of work.

These five job characteristics are presumed to influence critical psychological states. In turn, these psychological states are posited to directly influence four outcomes: (a) internal work motivation, (b) growth satisfaction, (c) general satisfaction, and (d) work effectiveness. It was

hypothesized that there are three moderators of the job characteristics/critical psychological states relationship and the critical psychological states/outcomes relationship. The most commonly examined moderator has been growth need strength (GNS). It was suggested that individuals high in GNS (e.g., the need for personal accomplishment) would react more favorably to enriched work. The two other moderators (individual knowledge and skill and context satisfaction) have been much less frequently studied.

Job characteristics theory and the motivational approach it represents rose to become the dominant perspective for research on job attitudes (Staw, 1984). Although some aspects of the model have failed to accumulate research support and there have been a number of criticisms (Roberts & Glick, 1981), these job characteristics have generally been found to have positive relationships with a variety of affective outcomes, and smaller relationships to behavioral outcomes (Fried & Ferris, 1987; Humphrey et al., 2007; Loher, Noe, Moeller, & Fitzgerald, 1985).

Sociotechnical Systems Theory

The sociotechnical systems approach arose from work conducted at the Tavistock Institute in Great Britain that focused on the use of autonomous groups to accomplish work (Trist & Bamforth, 1951). This perspective suggested that organizations are composed of people interacting with each other and a technical system to produce products or services. This interaction had a reciprocal and dynamic influence on the operation and appropriateness of the technology as well as the behavior of the people that operate it (Pasmore, Francis, Haldeman, & Shani, 1982). Given the interdependence between human and technical systems, sociotechnical systems theory suggested that productivity and satisfaction could be maximized via joint optimization. In other words, optimal organizational functioning would occur only if the social and technical systems were designed to fit each other (Trist, 1981).

Cummings (1978) suggested that sociotechnical design is appropriate when three conditions are satisfied. First, there must be adequate task differentiation such that the task(s) performed are autonomous and form a self-completing whole. This suggests a certain minimum of interdependence within the tasks themselves. Second, employees must have adequate boundary control, so they can influence and control transactions within the task environment. Finally, employees must be able to control the immediate task environment so they can regulate their behavior and convert raw materials into a finished product.

If these conditions for self-regulation are satisfied, Cherns (1978) suggests how to design work according to sociotechnical principles. First, the design process must be congruent with the design outcomes. For example, if increased participation and empowerment is one of the hoped-for outcomes of the work design, the process by which the work is designed should be participative and involve key stakeholders. Second, it is important to identify which tasks and objectives are essential, and that no more than is absolutely necessary be specified. Such minimal critical specification enables flexibility and the ability to respond to unanticipated circumstances. Third, the possibility of unexpected events suggests that if variance cannot be eliminated, it should be controlled as close as possible to its origin, suggesting that work be designed with sufficient autonomy or control. Fourth, in order to control variance at its source, workers must be multifunctional, have some level of control over “boundary tasks,” and have access to enough information to make decisions. Finally, from an organizational perspective, sociotechnical systems theory suggests that organizational systems should be congruent with the work design chosen. For example, if teams are employed, it might be important to have a compensation system that is based, in part, on team performance.

As these design principles suggest, the sociotechnical approach has a great deal in common with the job enlargement approach (Rousseau, 1977) in that it focuses on such things as autonomy, task feedback, and completing a whole piece of work. It differs, however, largely by focusing on the team level of analysis. In addition, although sociotechnical systems theory has a relatively long history, its key principles have not been completely tested and validated (e.g., such as joint optimization and controlling variance at its source). In fact, some have suggested that “it remains exceedingly difficult to specify propositions of the theory that are empirically disconfirmable” (Hackman, 1981, p. 80). Notwithstanding the foregoing, the sociotechnical approach is important because it formalized a focus on the group level of analysis and still exerts a strong influence on contemporary work design research and theory.

Social Information Processing Perspective

The social information processing approach of Salancik and Pfeffer (1978) arose from dissatisfaction with the need–satisfaction and expectancy models of motivation and job attitudes. Its importance for work design comes from the fact that it called attention to the effects of context and the consequences of past choices as opposed

to individual predispositions and rational decision-making processes.

The theoretical model was developed by Salancik and Pfeffer (1978) and subsequently examined in a number of studies in the 1970s and 1980s. The fundamental premise of the social information processing perspective is that individuals adapt their attitudes, behaviors, and beliefs to their social context as well as their past and present behavior and situation. This implies that the characteristics of work are not given but are constructed from social information. It also suggests that perceptions of job characteristics and reactions to work redesign may be influenced by factors besides objective features of work.

As summarized by Pfeffer (1981), the social information processing approach has four basic premises:

First, the individual’s social environment may provide cues as to which dimensions might be used to characterize the work environment . . . Second, the social environment may provide information concerning how the individual should weight the various dimensions—whether autonomy is more or less important than variety of skill, whether pay is more or less important than social usefulness or worth. Third, the social context provides cues concerning how others have come to evaluate the work environment on each of the selected dimensions . . . And fourth, it is possible that the social context provides direct evaluation of the work setting along positive or negative dimensions, leaving it to the individual to construct a rationale to make sense of the generally shared affective reaction. (p. 10)

Thus, the social environment impacts individuals in two ways. First, it helps individuals construct meaning about uncertain organizational features and events. It emphasizes what the socially acceptable beliefs and norms are, as well as the permissible forms of action given the organization’s broader context. Second, the social environment can direct attention by making certain information more salient. This provides information about expectations for individual behavior as well as the likely consequences of behavior. Generally speaking, research has found that social cues influence perceptions of and reactions to work, although there has been some debate about the magnitude of those effects (Kilduff & Regan, 1988).

Job Demands–Control–Support and Job Demands–Resources Models

Although perhaps most commonly discussed within the context of work stress and well-being, the Job Demands–Control–Support model (Karasek, 1979; Karasek & Theorell, 1990) and the Job Demands–Resources model

(JD-R; Bakker & Demerouti, 2007; Demerouti, Bakker, Nachreiner, & Schaufeli, 2001) have gained momentum in work design research. Originally developed by Karasek (1979), the job demands–control model attempts to shed light on the relationship between job demands and employee well-being outcomes, including physical illness, stress, strain, and burnout. The model proposes that job demands (i.e., any part of the job that requires sustained physical, psychological, or emotional effort) and job control (i.e., the amount of decision latitude one has) play a central role in determining the relationship between stressors and strain, such that job control buffers individuals from the negative effects of job demands. The model was later revised to include social support after researchers found that it, too, could play a buffering role in the stressor–strain relationship (Karasek & Theorell, 1990; Van Yperen & Hagedoorn, 2003). Research evidence testing the model has produced some conflicting results, with evidence suggesting that individual differences, including self-efficacy, proactive personality, and locus of control, can also play a key moderating role in the job demands–control relationship (Meier, Semmer, Elfering, & Jacobshagen, 2008; Parker & Sprigg, 1999; Salanova, Peiro, & Schaufeli, 2002). In addition, empirical results concerning the effects of social support have been similarly mixed. Although some studies have reported that social support reduces the impact of job demands on negative health effects, others have found no evidence supporting social support as a buffer to these negative outcomes (van der Doef & Maes, 1999).

Drawing from the tradition established by the Job Demands–Control–Support model, the Job Demands–Resources model was developed. This model recognizes both job demands and job resources as central tenets present in all organizational contexts. In contrast to the demands–control–support model, the JD-R model proposes that social support is but one type of job resource that, along with other types of resources (e.g., autonomy, feedback), can reduce employee disengagement and depersonalization by motivating workers, reducing job demands and their associated costs, and stimulating personal growth, learning, and development. In contrast, job demands (e.g., unfavorable physical environment, work pressure) increase emotional exhaustion (Bakker & Demerouti, 2007; Demerouti et al., 2001). Several studies have found evidence for the buffering effects of job resources. For example, Bakker, Demerouti, and Euwema (2005) found that employees high in autonomy, feedback, or social support did not experience the anticipated burnout associated with high levels of work overload,

emotional demands, physical demands, and work–home interference. Xanthopoulou and colleagues (2007) found similar results in a sample of employees working in home care organizations. Specifically, they found that high levels of job resources buffer the effects of job demands on burnout, with autonomy appearing to be the most important buffer, followed by support. Most recently, Nahrgang, Morgeson, and Hofmann (2011) meta-analytically tested the relationship between job demands and job resources, and burnout, engagement, and safety outcomes. They found that job demands in the form of complexity and risks and hazards were significantly related to burnout ($r_c = 0.24$ and $r_c = 0.28$, respectively), and negatively related to engagement ($r_c = -0.52$ and $r_c = -0.67$, respectively). In contrast, job resources in the form of knowledge, social support, leadership, and safety climate were significantly related to engagement (ranges of r_c from 0.47 to 0.80), and significantly and negatively related to burnout (ranges of r_c from -0.24 to -0.39).

Interdisciplinary Model of Job Design

Recognizing that work design research in I-O psychology was focused almost exclusively on motivationally oriented approaches, Campion outlined an interdisciplinary model of job design (Campion 1988, 1989; Campion & Thayer, 1985). This perspective suggests that different scientific disciplines have produced several distinct approaches to job design and research in each approach has been conducted relatively independently of other approaches. The interdisciplinary job design perspective highlights this fact and suggests that there are at least four basic approaches, each focusing on a distinct set of outcomes.

Grounded in classical industrial engineering research (e.g., Barnes, 1980; Gilbreth, 1911; Taylor, 1911), the *mechanistic model* evolved largely to deal with the pressures for efficiency that arose during the industrial revolution. This approach recommended increased simplification, specialization, and repetition of work. These changes were intended to result in increased efficiency, easier staffing, reduced training costs, and lowered compensation requirements.

Proceeding primarily from research in organizational psychology (e.g., Hackman & Oldham, 1980; Herzberg et al., 1959), the *motivational model* evolved in response to job dissatisfaction, the deskilling of industrial jobs, and alienation of workers that resulted from the over-application of the mechanistic model. The approach usually provides “job-enriching” recommendations such as increasing the variety of tasks performed or the autonomy

with which they are executed. The intended benefits of this model include increased job satisfaction, intrinsic motivation, retention, and customer service.

Based on human factors and experimental psychology research (e.g., Fogel, 1967; McCormick, 1976; Meister, 1971), the *perceptual model* arose from increases in technological complexity and a shift in many jobs from manually performing work to operating and monitoring. This approach is primarily concerned with reducing the information processing requirements of work in order to reduce the likelihood of errors, accidents, and mental overload.

Emerging from ergonomics and medical sciences research (e.g., Astrand & Rodahl, 1977; Grandjean, 1980), the biological model sought to alleviate physical stresses of work. Reductions in physical requirements and environmental stressors and increased consideration of postural factors are common recommendations. Taking these factors into account when designing jobs can reduce physical discomfort, physical stress, and fatigue.

CONTEXTUAL INFLUENCES ON WORK DESIGN

As noted by Morgeson, Dierdorff, and Hmurovic (2010, p. 351), “despite nearly 100 years of scientific study, comparatively little attention has been given to articulating how the broader occupational and organizational context might impact work design.” Morgeson and colleagues suggest that this failure to recognize the broader occupational and organizational environment is unfortunate for two main reasons. First, as indicated by recent empirical findings, work roles, and as a result their related work designs, are susceptible to a variety of contextual elements (Dierdorff & Morgeson, 2007; Dierdorff, Rubin, & Morgeson, 2009). Second, given that different work contexts are likely to influence individual needs and behaviors, they are also likely to impact the relationships between work design features and outcomes.

Recent meta-analytic findings by Humphrey et al. (2007) support the idea that contextual work design features are an important yet understudied area in work design research. They found that physical demands were negatively related to job satisfaction ($r_c = -0.17$), whereas work conditions were positively related to job satisfaction ($r_c = 0.23$) and negatively related to stress ($r_c = -0.42$). Despite a limited number of studies that looked at the work context, results from their hierarchical regression provide evidence for the incremental prediction of the contextual characteristics above and beyond motivational and social characteristics. Impressively, work

conditions alone explained an incremental 16% of the variance in stress. Collectively, these results suggest that contextual elements are indeed fruitful areas for research in work design. In the following sections, we highlight several elements of the social and structural context and discuss their implications for work design.

Social Influences

Spurred on by the social information processing model of Salancik and Pfeffer (1978), a host of researchers have examined the influence social information might have on work design perceptions and outcomes. The first research was conducted in laboratory settings and served to demonstrate that social information could impact task perceptions and task satisfaction. Although some found stronger effects for task enrichment (Weiss & Shaw, 1979), others suggested that social cues were more important for affective outcomes (O’Reilly & Caldwell, 1979; White & Mitchell, 1979). Of course, in this lab research the strengths of task and social cue manipulations are experimentally controlled. Thus, discussions about relative importance in fixed effects designs are not warranted.

Using a more extensive and complex within-subjects design, Griffin, Bateman, Wayne, and Head (1987) found that enriched tasks, coupled with positive social information cues, were the most motivating. This suggests that both objective facets of the work environment and social information determine perceptions and affect. Similarly, Seers and Graen (1984) found that including both task and leadership characteristics improved prediction of performance and satisfaction outcomes.

Other research has sought to define the range of situations under which social information can influence work design. Caldwell and O’Reilly (1982) found that an individual’s job satisfaction is related to perceptions of task characteristics. Adler, Skov, and Salvemini (1985) reached a similar conclusion when they found that manipulating job satisfaction affects perceptions of task scope. Using an equity theory perspective, Oldham and colleagues (Oldham et al., 1982; Oldham, Kulik, Ambrose, Stepina, & Brand, 1986; Oldham & Miller, 1979) have sought to understand the consequences of different social comparisons in the workplace. Oldham et al. (1982) found that individuals do make comparisons to others in the work setting, and they tend to select more complex jobs as their referent. Oldham et al. (1986) then found that employees who felt disadvantaged relative to their referents were typically less satisfied and less internally motivated but employees who felt advantaged or equitable relative

to their referents performed at higher levels, were absent less frequently, and withdrew from the organization less frequently.

Two final studies in this area deserve attention. First, Vance and Biddle (1985) not only looked at the influence of social cues on task attitudes, but also investigated the timing of the social cues. They found that task-related attitudes were influenced by social cues, but the impact of those social cues was lessened with experience with the task. This suggests that social cues are more important before subjects have the opportunity to acquire many “objective” cues. Second, Kilduff and Regan (1988) found that although positive and negative cues impacted perceptions of task characteristics, they had no influence on actual behavior. They concluded that although ratings of tasks were responsive to information cues, actual behavior was responsive to direct experience with the task.

To test congruency model predictions, Pierce, Dunham, and Blackburn (1979) conducted a field study looking at the relative impact of social system design (organic or mechanistic) and job design on job satisfaction. They found that workers had the highest satisfaction when they had complex jobs in organic organizational structures (i.e., participative, few rules). Interestingly, the second highest levels of satisfaction were from workers who had complex jobs in mechanistic organizational structures. This suggests that features of the work itself are more important than social system factors for affective reactions.

In a field experiment, Griffin (1983) directly examined the relative impact of social cues and task changes. He found that social cues had a greater impact on social outcomes (e.g., friendship opportunities, dealing with others) and that the task manipulation had a greater effect on task characteristics. Both social cues and task changes impacted intrinsic, extrinsic, and overall satisfaction, although the task changes had a larger effect. Only the task changes, however, impacted productivity.

Structural Influences

Work occurs within the context of a larger organizational system, where many aspects of these systems influence the ways in which it is designed. For example, organizations that are highly decentralized are likely to design work to be more autonomous given the philosophy that underlies decentralized work structures. Because of this, researchers have continued to gain a better understanding of the mechanisms through which structural factors impact work design.

Early work on organizational structure found that such things as formalization and centralization were negatively

related to perceptions of several job characteristics (e.g., autonomy, variety, feedback, and identity; Pierce & Dunham, 1978a). Similar results were obtained in a study by Rousseau (1978a), who found negative relationships between several aspects of departmental structure (size, centralization, and formalization) and job characteristics and satisfaction. Rousseau (1978b) also found that job characteristics such as variety and autonomy mediated the relationship between the technological and structural context of the organization and employee outcomes like satisfaction and motivation. Evidence for mediation has been supported in a number of different studies (e.g., Brass, 1981; Oldham & Hackman, 1981; Pierce, 1979). For example, Oldham and Hackman (1981) found that job characteristics mediated the relationship between organizational structure and employee reactions of growth, pay, and supervisory satisfaction.

Over the course of a three-year quasi-experimental field study, Parker (2003) found that the use of three lean production practices (i.e., lean teams, assembly lines, and workflow formalization and standardization) negatively impacted employees. Results indicated that although workers in all three lean production groups were negatively impacted, with all groups reporting poorer quality work design, this was especially true for assembly-line workers. This group showed a decrease in organizational commitment as well as an increase in job depression. Based on results from meditational analyses, Parker also showed that the negative effects of lean production were at least partly due to a decline in employee perceptions of positive work characteristics (e.g., autonomy, skill utilization, participation in decision-making).

Another important structural element is that of the physical environment. In their quasi-experiment, Oldham and Brass (1979) examined how the physical environment affected job characteristics in a sample of workers at a newspaper organization who moved from a traditional office setting to an open-plan office arrangement (i.e., offices with no interior walls or partitions). Even though there were no changes to the jobs themselves, moving to a new office decreased the perception of several job characteristics (e.g., task significance, task identity). As in other studies, Oldham and Brass (1979) found that job characteristics mediated the relationship between the physical setting and reduced worker satisfaction and motivation. They suggested that the physical setting influences employee motivation and satisfaction by changing perceptions of specific job characteristics.

The technological environment is another potentially important structural feature of the work environment. In

a direct test of the relative influence of job design, structure, technology, and leader behavior, Pierce, Dunham, and Cummings (1984) found that job design (particularly autonomy and variety) was the primary predictor of employee attitudes and behavior and that technology was the second most important. They suggested that job design is most important because it is much “closer” to the worker and is experienced on a more direct and regular basis.

Recent meta-analytic evidence supports the notion that technology can influence work design and individual-level outcomes. Gajendran and Harrison (2007) found that telecommuting (a type of virtual work arrangement) increased perceived autonomy, job satisfaction, and performance. In addition, it reduced work–family conflict, turnover intentions, and role stress. More recently, Gibson, Gibbs, Stanko, Tesluk, and Cohen (2011) found that the effects of motivating job characteristics (e.g., task significance, autonomy, and feedback) on experienced meaningfulness, responsibility, and knowledge of results were dependent on workplace virtuality (i.e., electronic dependence and a lack of copresence). They found that virtual features of work enhanced the relationship between task significance and experienced meaningfulness but decreased the relationship between autonomy and responsibility. Similar results were found for the relationship between feedback and knowledge of results, with the relationship being weaker in highly electronically dependent settings. Taken together, these results suggest that technological aspects of the organizational context merit additional research attention.

Another component of the organizational context that seems especially relevant, but that has failed to receive attention in work design research, is that of error criticality. Error criticality represents the extent to which incorrect task performance can result in negative consequences (Brannick, Levine, & Morgeson, 2007). Although all roles contain some degree of error criticality, it is especially salient in jobs where incorrect task performance has negative implications to the self or others. For example, if a nurse incorrectly administers a dose of medication, the outcome could be disastrous, potentially resulting in the death of a patient. As highlighted by Morgeson and Humphrey (2008), employees in high error criticality contexts are more likely to focus on preventing errors rather than on obtaining positive outcomes. Regulatory focus research suggests that when one focuses on prevention rather than promotion, the predominant motivational state will be to avoid making mistakes (Lieberman, Molden, Idson, & Higgins, 2001). Because the potential

consequences are so great when error criticality is high, its discrete contextual influence can shift an individual’s focus to that of preventing errors. When motivated to prevent errors, individuals also are likely to seek to minimize personal accountability, leading to further risk avoidance (Tetlock & Boettger, 1994; Weigold & Schlenker, 1991). This suggests that as an element of the task context, error criticality may constrain employee reactions to work design features such that when error criticality is high, typically positive work characteristics that increase responsibility and accountability (e.g., autonomy, problem solving, job complexity) may be seen as less desirable.

CHARACTERISTICS OF WORK

A large body of research has investigated the ways in which work can be described and the issues that arise when attempting to describe work. This section begins with a discussion of the structure of work, followed by a consideration of whether objective features or subjective perceptions of work are being measured in work design research, and concludes with a consideration of potential measurement problems in the research literature.

Structure of Work

Perhaps one of the most important aspects to designing and redesigning work revolves around understanding its structure. This importance is best illustrated in the literally thousands of studies looking at work design issues. Despite such efforts, research on the measurement of work characteristics has been narrow, incomplete, and problematic (Morgeson & Humphrey, 2006). To address such weaknesses Morgeson and Humphrey (2006) undertook an extensive review of the literature, and in so doing identified an extended list of work characteristics. Based on their findings, they developed a new measure of work design (called the Work Design Questionnaire [WDQ]) that assesses a wide range of work characteristics. Their efforts and the resulting WDQ are discussed in detail below.

Toward a Comprehensive Measure of Work Design

The WDQ was developed in part to address the narrow set of work characteristics measured in traditional work design research. As suggested by Parker, Wall, and Cordery (2001), “Consideration of modern forms of work and employment indicates the need to encompass a wider

range of work characteristics” (p. 422). Morgeson and Humphrey (2006) argue that a measure of work design that includes a variety of work characteristics is needed for several reasons. First, prior measures have been either too specific (e.g., task measures) or too general (e.g., attribute measures), failing to capture the middle ground in between them. Second, by including only a limited number of motivational job characteristics, work design efforts are likely to be highly restricted. By looking at an expanded set of characteristics more fine-grained changes can be made to the design of work (Morgeson & Campion, 2002). Finally, a measure of work that recognizes motivational, social, and work context elements may help encourage researchers to pursue new theoretical models.

For example, the Job Diagnostic Survey (JDS; Hackman & Oldham, 1980), the most commonly used work design measure, looks at only five motivational work characteristics: skill variety, task identity, task significance, autonomy, and feedback from the job. This is problematic for two main reasons. First, reliance on a measure with such a narrow set of work characteristics has resulted in work design research that neglects other potentially important work elements. Second, despite considerable efforts to replicate the five-factor structure, most studies have reported inconsistent factor solutions and have identified several problems with the factor structure of the JDS (Dunham, 1976; Dunham, Aldag, & Brief, 1977; Harvey, Billings, & Nilan, 1985; Idaszak & Drasgow, 1987; Kulik, Oldham, & Langer, 1988). Subsequent work by Sims, Szilagyi, and Keller (1976) resulted in the job characteristics inventory (JCI). Although findings indicated that this measure was superior to the JDS in terms of internal consistency and dimensionality (Pierce & Dunham, 1978b), it was largely based on items taken from the work of Hackman and Lawler (1971). As a result, the six factors (variety, feedback, dealing with others, task identity, and friendship) were quite similar to those in the JDS.

Recognizing the parochial nature of work design research, Campion (1988; Campion & Thayer, 1985) developed the Multimethod Job Design Questionnaire (MJDQ) to explicitly include other views of work in addition to the commonly measured motivational perspective. Although it measured a greater variety of work characteristics, the MJDQ suffered from measurement issues and gaps in construct measurement (Edwards, Scully, & Brtek, 1999, 2000). Edwards et al. (1999) found that in contrast to the four-factor structure (corresponding to the four distinct job design approaches) proposed by Campion (1988), a 10-factor model best fit the data, achieved discriminant validity, and produced adequate reliabilities. The

mechanistic approach included specialization and task simplicity scales; the motivational approach included feedback, skill, and rewards scales; the perceptual-motor approach included ergonomic design and cognitive simplicity scales; and the biological approach included physical ease, work conditions, and work scheduling scales. Despite such efforts, the MJDQ was still limited because the 10 scales did not fully represent the dimensions relevant to each work design approach. In addition, because some of the items from the MJDQ are the sole indicators of a given work dimension (e.g., a single item is used to represent autonomy), they cannot be used to form scales. As a result, additional items would need to be developed so these dimensions of work could be measured.

In addition to these specific measures—JDS, JDI, and MJDQ—other research has attempted to clarify and expand our understanding of numerous work characteristics (e.g., Kiggundu, 1983; Stone & Gueutal, 1985; Wong & Campion, 1991). Despite such efforts, it remains unclear how these work characteristics relate to other work elements, thus limiting our understanding of work design. The WDQ was developed to address the limitations present in existing measures.

The Work Design Questionnaire (WDQ)

With a consideration of the strengths and weaknesses of past measures, Morgeson and Humphrey (2006) set out to develop and validate a comprehensive measure of work design. This process began with a thorough search for all articles related to job or work design followed by a review of the Occupational Information Network (O*NET) job analysis database. Based on their findings, the authors identified 107 different work characteristics. Using a structured sorting and classification process, this original list was shortened to 18 work characteristic categories (see Morgeson and Humphrey, 2006, for a detailed explanation of the methodology used). These 18 work characteristics were then placed into one of four major categories: task, knowledge, social, and contextual. Each of these categories and the subsequent work characteristics within each are discussed below. See Table 20.1 for a brief definition of each of the 18 work characteristics.

Task Characteristics

Typically the most commonly investigated motivational work design characteristic, task characteristics focus on how the work itself is accomplished. It involves understanding the range and nature of the tasks associated with a given job. Of the task characteristics, autonomy has

TABLE 20.1 WDQ Work Characteristic Definitions

WDQ Category	Dimension	Definition
Task Characteristics	Autonomy	Extent to which a job allows freedom, independence, and discretion over work scheduling, decision making, and work methods.
	Task Variety	Degree to which a job requires employees to perform a wide range of tasks on the job.
	Task Significance	Degree to which a job influences the lives or work of others, whether inside or outside the organization.
	Task Identity	Degree to which a job involves a whole piece of work, the results of which can be easily identified.
	Feedback from Job	Degree to which the job provides direct and clear information about the effectiveness of task performance.
Knowledge Characteristics	Job Complexity	Extent to which the tasks on a job are complex and difficult to perform.
	Information Processing	Amount of information processing needed at work reflects the degree to which a job requires attending to and processing data or other information.
	Problem Solving	Degree to which a job requires unique ideas or solutions and reflects the more active cognitive processing requirements of a job.
	Skill Variety	Extent to which a job requires an individual to use a variety of different skills to complete the work.
	Specialization	Extent to which a job involves performing specialized tasks or possessing specialized knowledge and skill.
Social Characteristics	Social Support	Degree to which a job provides opportunities for advice and assistance from others.
	Interdependence	Degree to which the job depends on others and others depend on it to complete the work.
	Interaction Outside the Organization	Extent to which the job requires employees to interact and communicate with individuals external to the organization.
	Feedback from Others	Degree to which others in the organization provide information about performance.
Contextual Characteristics	Ergonomics	Degree to which a job allows correct or appropriate posture and movement.
	Physical Demands	Degree of physical activity or effort required in the job.
	Work Conditions	Elements of the environment within which a job is performed.
	Equipment Use	Variety and complexity of the technology and equipment used in a job.

garnered the most research attention (Morgeson & Humphrey, 2006). Based on the work of Wall and colleagues, autonomy has been operationalized as multifaceted, reflecting the degree of freedom one has over one's work scheduling, decision-making, and work methods (Breugh, 1985; Wall, Jackson, & Davids, 1992). *Work scheduling autonomy* reflects the ability to control the timing of one's work. *Decision-making autonomy* reflects the ability to make decisions at work. *Work methods autonomy* represents the ability to control how the work is performed. Meta-analytic evidence suggests that autonomy is indeed a key workplace characteristic, reducing anxiety, stress, and burnout ($p = -0.10$, $p = -0.23$, and $p = -0.30$, respectively; Humphrey et al., 2007). In addition, it is related to several important attitudinal outcomes, including job satisfaction, organizational commitment, and work

motivation ($p = 0.48$, $p = 0.37$, and $p = 0.38$, respectively).

Task variety is similar to that of task enlargement as defined in prior research (Herzberg, 1968; Lawler, 1969), with the notion being that jobs that involve a number of different work activities are more enjoyable and interesting (Sims et al., 1976). Thus, not surprisingly, Humphrey et al. (2007) found task variety to be related to job satisfaction, and subjective ratings of performance ($p = 0.46$ and $p = 0.23$, respectively).

Task significance reflects the impact one's work has on others. Recent work by Grant has brought renewed attention to task significance (Grant, 2008a, 2008b). As with other task characteristics, task significance is related to several important outcomes, including job satisfaction, organizational commitment, and work motivation ($p = 0.41$,

$p = 0.44$, and $p = 0.45$, respectively; Humphrey et al., 2007). In addition, task significance has a negative relationship with burnout ($p = -0.29$), and a positive relationship with perceptions of overload ($p = 0.38$). Morgeson and Humphrey (2008) suggest that the link between task significance and overload may indicate that workers high in task significance are overloaded by the weight of their responsibilities.

Task identity centers on the importance of being able to complete an entire unit of work versus completing only a small part of the task. Early research suggested that the ability to complete a piece of work from beginning to end leaves workers with a sense of pride and provides a source of motivation (Hackman & Oldham, 1976). Although meta-analytic evidence has found smaller effect sizes for task identity and worker motivation, organizational commitment, and job satisfaction ($p = 0.26$, $p = 0.19$, and $p = 0.31$, respectively), future research is warranted given its relationship to burnout and subject performance evaluations ($p = -0.28$ and $p = 0.17$, respectively; Humphrey et al., 2007). Recent work by Christian, Garza, and Slaughter (2011) found a strong relationship between task significance and employee work engagement ($p = 0.51$). This would suggest that organizations interested in increasing employee engagement may want to consider designing or redesigning jobs to include a greater amount of task identity.

Feedback from the job focuses on feedback obtained from either the job itself or knowledge of one's work activities (Morgeson & Humphrey, 2006). In line with goal-setting theory (Locke & Latham, 1990), feedback plays a central motivational role by helping workers adjust their behaviors based on the goals that they hold (Vancouver, 2005). Thus, not surprisingly, meta-analytic results (Humphrey et al., 2007) found that feedback from the job has a strong positive relationship with work motivation ($p = 0.42$) and job satisfaction ($p = 0.43$). Humphrey et al. (2007) also found that feedback from the job was negatively related to a handful of outcomes, including anxiety ($p = -0.32$).

Knowledge Characteristics

Knowledge characteristics encompass knowledge, skill, or ability demands placed on a worker as a result of the job (Morgeson & Humphrey, 2006). As suggested by Campion and McClelland (1993), separating task and knowledge characteristics acknowledges that a job can be designed or redesigned to increase either task demands, knowledge demands, or both.

Job complexity (the inverse of job simplicity; Campion, 1988) was originally conceptualized as an aspect of mechanistic job design. Morgeson and Humphrey (2006), however, found that job complexity was a distinct construct with varying effects on work outcomes. They suggest that work high in job complexity involves the use of high-level skills and is more mentally and physically challenging. Meta-analytic results would seem to suggest that this is indeed the case. Humphrey et al. (2007) found a positive relationship between job complexity and job satisfaction ($p = 0.37$), job involvement ($p = 0.24$), and perceptions of overload ($p = 0.59$).

Information processing derives from the work of Wall and colleagues (Martin & Wall, 1989; Wall & Jackson, 1995; Wall, Jackson, & Mullarkey, 1995). This stream of research suggests that information processing and monitoring vary across jobs, with knowledge requirements highest in jobs that have information processing requirements. This would seem to fit with evidence demonstrating that information processing increases compensation and training requirements ($r = 0.37$ and $r = 0.33$, respectively). Thus, Morgeson and Humphrey (2008) suggest that although information processing may likely lead to greater worker learning and development, it may also serve to increase the skill requirements needed on the job.

Problem solving involves generating unique or innovative ideas, solving nonroutine problems, and preventing or recovering from errors (P. R. Jackson, Wall, Martin, & Davids, 1993; Morgeson & Humphrey, 2006; Wall et al., 1995). This is similar to the idea of creativity. Although limited empirical research has been conducted in the area, recent meta-analytic evidence found that problem solving was related to work engagement ($p = 0.28$; Christian et al., 2011).

Skill variety differs from task variety in that it reflects the use of multiple skills versus the performance of multiple tasks (Morgeson & Humphrey, 2006). Hackman and Oldham (1976) suggested that the use of multiple skills is more challenging and thus more engaging to perform. Humphrey et al. (2007) found that skill variety is related to worker motivation ($p = 0.42$), job involvement ($p = 0.30$), and job satisfaction ($p = 0.42$). Yet, skill variety was not related to any of the behavioral, cognitive, or well-being outcomes examined in the meta-analysis.

Specialization is conceptually distinct from both task and skill variety in that it refers to the depth of knowledge and skill required to complete a job (Morgeson & Humphrey, 2008). Despite only a handful of studies having looked at specialization (e.g., Campion, 1988; Edwards et al., 2000; Morgeson & Humphrey, 2006),

work by Morgeson and Campion (2002) seems to suggest that it is related to both efficiency and job satisfaction.

Social Characteristics

Social characteristics represent the broader social environment within which work is performed. Although historically these dimensions of work have been less studied than motivational characteristics, scholars have emphasized the importance of giving more serious consideration to social and relational elements (Grant & Parker, 2009). Researchers suggest that social elements are deserving of more attention given the increasingly important role of workplace social relationships, the collaborative nature of teams, and growth in the service sector requiring employees to interact with customers, clients, and patients (Grant & Parker, 2009).

Social support includes supervisor and coworker social support (Karasek, 1979; Karasek et al., 1998) as well as friendship opportunities at work (Sims et al., 1976). Past research has discussed the role of social support in terms of its ability to buffer employees from negative work outcomes (Johnson & Hall, 1988; Karasek et al., 1998), with empirical results suggesting that social support plays a critical role in employee well-being (Ryan & Deci, 2001; Wrzesniewski, Dutton, & Debebe, 2003). This was supported by recent meta-analytic evidence, which found a small to moderate negative relationship with well-being outcomes (Humphrey et al., 2007). Not surprisingly, Christian and colleagues (2011) found that social support was moderately related to work engagement ($p = 0.32$). In addition, Humphrey et al. (2007) found that social support was strongly related to organizational commitment, job satisfaction, and turnover intentions ($p = 0.82$, $p = 0.56$, and $p = -0.32$, respectively). Finally, they found that social support is negatively related to role perceptions, including role ambiguity ($p = -0.32$) and role conflict ($p = -0.31$).

Interdependence is a multifaceted construct reflecting the structural “connectedness” of jobs to each other. This involves the extent to which a job has tasks that flow to other jobs (i.e., initiated interdependence) and the extent to which a job obtains or receives tasks from other jobs (i.e., received interdependence; Kiggundu, 1981). Previous research has looked at combinations of initiated and received interdependence and the extent to which this creates more complex forms of interdependence. Thompson (1967) looked at sequential interdependence, described as a unidirectional flow of initiated and received interdependence, whereas Van de Ven, Delbecq, and Koenig (1976)

explored the role of intensive interdependence in which the flow of behaviors goes to and from all team members. Another important consideration is whether interdependence takes place between jobs, teams, or organizations. Depending on the parties involved, more complex coordination, information sharing, and resource exchange issues may arise. Although interdependence has been shown to mainly affect attitudinal outcomes such as satisfaction and organizational commitment (Campion, Medsker, & Higgs, 1993; Humphrey et al., 2007), because interdependence requires higher levels of implicit coordination (Rico, Sanchez-Manzanares, Gil, & Gibson, 2008), it often causes workers to also perceive higher levels of overload (Humphrey et al., 2007). Yet, it is important to acknowledge that often as a result of interdependence tacit job knowledge is transferred (Berman, Down, & Hill, 2002), resulting in higher job performance (Humphrey et al., 2007; Saavedra, Earley, & Van Dyne, 1993).

Interaction outside the organization differs from other social characteristics because it focuses on communication between organizational members and nonorganizational members rather than solely on within-organization information exchange. In this way, interaction outside the organization encompasses a much broader social environment, with interactions taking place between suppliers, customers, or any other numerous external parties. Much less is known about this particular social characteristic in contrast to other social elements. Although recent work by Humphrey et al. (2007) has shown that it is related to higher job satisfaction, Morgeson and Humphrey (2006) have also shown that it is related to increased compensation requirements.

Feedback from others differs from feedback from the job in that it recognizes that feedback often comes from multiple sources, including other individuals (Hackman & Lawler, 1971). This distinction is important given recent work by Morgeson and Humphrey (2006), which shows that feedback from the job and feedback from others are only moderately related. Because feedback from others arises out of the larger social context, two potentially important sources of feedback are coworkers and supervisors. For example, role theory research suggests that supervisory feedback can reduce ambiguity by helping to establish and clarify role expectations (Biddle, 1979; Kahn, Wolfe, Quinn, Snoek, & Rosenthal, 1964). It follows, then, that this element is positively related to a host of beneficial outcomes, including well-being, satisfaction, and work motivation, and is negatively related to turnover intentions and stress (Humphrey et al., 2007).

Contextual Characteristics

Contextual characteristics represent the physical and environmental context within which the work is performed. Early work by Campion (1988) highlighted the importance of *ergonomics* (i.e., the extent to which work allows for correct posture and movement) as an element of the context. Researchers have continued to look at the role of ergonomics, with results indicating that it is related to job satisfaction (Morgeson & Humphrey, 2006) and efficiency (Edwards et al., 2000). As noted by Morgeson and Humphrey (2008), both *physical demands* and *work conditions* (e.g., health hazards, noise, temperature, and cleanliness of the work environment) are often identified as having a key influence on outcomes. For example, Humphrey et al. (2007) found that whereas physical demands have a negative impact on job satisfaction ($p = -0.17$), work conditions have a positive influence ($p = 0.23$). Recent meta-analytic findings show that physical demands and work conditions are negatively related to employee work engagement ($p = -0.23$ and $p = -0.22$, respectively; Christian et al., 2011), and risks and hazards (e.g., noise, dust, heat, chemicals, and hazardous tools and equipment) are positively related to burnout but negatively related to engagement ($r_c = 0.28$ and $r_c = -0.67$, respectively; Nahrgang et al., 2011). The last of the contextual characteristics, *equipment use*, has not been previously assessed by other job design measures. However, previous research has suggested the importance of giving more attention to the equipment and technology used at work (Goodman, 1986; Harvey, Friedman, Hakel, & Cornelius, 1988). Hopefully its inclusion within the WDQ will provide researchers with the tool to explore this largely unrecognized contextual characteristic.

Summary

Until recently, past measures of work design considered only a narrow set of work characteristics, limiting work design researchers' ability to explore a wider range of work elements. As discussed above, the Work Design Questionnaire (WDQ) attempts to remedy this issue by providing the most exhaustive and comprehensive measure consisting of 18 work characteristics. Morgeson and Humphrey (2006) validated the WDQ in a sample of 540 incumbents across 243 different jobs. They found that the WDQ demonstrated excellent reliability and convergent and discriminate validity. In addition, although only recently published, the WDQ or subsets of the measure have been used in several empirical studies (e.g., Chung-Yan, 2010; Grant, 2008a; Grant & Sonnentag, 2010)

and it is beginning to be translated into other languages (Stegmann et al., 2010). We are hopeful that the WDQ will continue to play a role in future work design research that seeks to explore a wide range of work characteristics.

Objective Characteristics Versus Subjective Perceptions

Having described the various dimensions included in both past and recent measures of work design, we now move to concerns around the validity of job incumbent self-reports. That is, when job incumbents provide ratings about their job, do these ratings reflect objective properties of the job, or are they fundamentally subjective perceptions that may or may not be isomorphic with the actual job duties and responsibilities (Shaw, 1980)? As we have seen, a variety of factors can impact work design perceptions. Although early work in this area suggested that employee perceptions "are causal in affecting the reactions of employees to their work" (Hackman & Lawler, 1971, p. 269), it has always been assumed that these perceptions converge with an objective reality. In fact, Hackman and Oldham (1975) suggested that their Job Diagnostic Survey provides a measure of objective job dimensions when completed by job incumbents. In any event, it is presumed that objective task properties are related to perceived task properties (Taber & Taylor, 1990). This question has been investigated in two different ways.

Convergent Validity

The first way researchers have investigated this question is by examining the convergence between different sources of job information. This includes convergence between job incumbent self-reports and ratings made by others (e.g., supervisors, observers, job analysts) as well as convergence with published job information (e.g., job analysis databases). Presumably, ratings made by individuals who are not currently performing the job would be less subject to biases or perceptual distortions, and convergence with existing job analysis databases would reflect convergence to a more objective reality.

A large number of studies have investigated this issue (Algera, 1983; Birnbaum, Fargh, & Wong, 1986; Brass, 1981; Brief & Aldag, 1978; Gerhart, 1988; Gould, 1979; Griffin, 1981; Hackman & Lawler, 1971; Hackman & Oldham, 1975; Hackman, Pearce, & Wolfe, 1978; Jenkins, Nadler, Lawler, & Cammann, 1975; Kiggundu, 1980; Oldham, 1976; Oldham, Hackman, & Pearce, 1976; Spector, Dwyer, & Jex, 1988; Spector & Jex, 1991; Stone, 1975,

1976; Stone & Porter, 1975, 1978). Several have found relatively strong relationships between employee and supervisory ratings. For example, Oldham et al. (1976) found job-level correlations between supervisors and employees up to 0.85. Hackman and Lawler (1971) also found relatively high convergence between employees, supervisors, and researchers on the job dimensions of variety and autonomy (correlations in the 0.80s and 0.90s). Lower convergence was found with respect to feedback and dealing with others.

Others have found smaller convergence. For example, Birnbaum et al. (1986) found moderate to low correlations between incumbents and supervisors, ranging from 0.20 to 0.62. Again, variety and autonomy evidenced the highest convergence. Hackman and Oldham (1975) examined convergence between employees and supervisors, employees and observers, and supervisors and observers. The median correlations at the job level were 0.51, 0.63, and 0.46, respectively. Although there was moderate convergence across the sources, some job dimensions had low or negative relationships.

Several researchers (Campion, 1989; Dunham, 1977; Gerhart, 1988; Morgeson & Humphrey, 2006; Rousseau, 1982; Schneider, Reichers, & Mitchell, 1982; Taber, Beehr, & Walsh, 1985) have investigated the convergence between incumbent perceptions of job characteristics and other job information (e.g., job analysis databases, job evaluation systems). They found modest convergence between these sources, again suggesting that incumbent self-reports are anchored in some level of objective reality. Spector and Jex (1991) compared employee perceptions to the Dictionary of Occupational Titles (DOT)-derived complexity ratings, as well as ratings made by independent raters. Although they found moderate convergence between DOT measures and independent raters, there was smaller convergence between employee perceptions and the other two sources of information. Spector, Fox, and Van Katwyk (1999) found very little convergence between incumbent ratings and job analyst or supervisor ratings. Only 4 of 10 comparisons were significant, and the strongest correlation was 0.27.

In their meta-analysis of job design research, Fried and Ferris (1987) concluded that there was moderate to good overlap between incumbent ratings of job characteristics and those made by other raters. Spector (1992) conducted a more focused meta-analysis of 16 convergence studies, separating studies that assessed individual level (where the incumbent was the unit of analysis) versus aggregate-level (where the job was the unit of analysis) convergence. In general, convergence was greater at the job level, which

might be expected given that idiosyncratic differences between incumbents would be eliminated by aggregating. At the job level, the mean correlation was 0.59, with autonomy and variety evidencing the highest relationships (0.71 and 0.74, respectively). At the individual level, however, convergence was considerably lower. The mean correlation was 0.22, with autonomy and variety again evidencing the highest relationships (0.30 and 0.46, respectively). Across both the individual and aggregate level, however, incumbents and observers generally fail to converge in their ratings of feedback. Given this evidence, Spector (1992) suggested a conservative lower bound estimate of 10% to 20% as the amount of variance that could be attributed to the objective job environment.

There are three additional points to understand with respect to the studies that demonstrate convergence between different sources. First, higher levels of convergence at the aggregate level may be inflated because of aggregation bias (James, 1982). Correlations computed at the job level will typically be much higher than those computed at the individual level, regardless of actual levels of convergence. This increased convergence at the job level results from increased reliability, which is a function of the number of respondents, the correlation between respondents, and between-job variance.

Second, because convergence is indexed through correlations between different sources, it reflects patterns of covariance. That is, when a job incumbent rates autonomy high, so too does his or her supervisor. Issues of covariance, however, are independent of the absolute level of agreement across raters. In other words, although incumbents and supervisors may evidence distinct patterns of covariation in their ratings, the correlation between their ratings does not index the extent to which raters make similar mean-level ratings (Kozłowski & Hattrup, 1992). This suggests that high convergence may not reflect high agreement. This is an issue that has received some research attention (Sanchez, Zamora, & Viswesvaran, 1997).

Third, a lack of convergence may be due to real changes workers make to their jobs. Some workers may expand their job so that they integrate additional task elements into their role (Ilgen & Hollenbeck, 1991; Morgeson, Delaney-Klinger, & Hemingway, 2005). For example, Campion and McClelland (1993) found that incumbents often made their work more mechanistic. Such job crafting (Wrzesniewski & Dutton, 2001) would attenuate the relationship between self-reports and other reports because workers may change their jobs in ways known only to them.

Manipulation of Job Properties

The second way researchers have sought to determine whether self-reports of job characteristics reflect an objective reality or are simply subjective perceptions has been to alter or modify aspects of work, and then look for corresponding changes in incumbent perceptions. To the extent that job incumbents recognize objective changes in their work, we can be confident that their perceptions are anchored in reality. It is important to recognize, however, that such changes can provide only an approximate estimate of the degree to which variance in incumbent perceptions is caused by objective differences in jobs. This is due to the fact that the manipulated job characteristics in the literature tend not to be representative of the full range of characteristics in the work environment (i.e., a true random effects design; Taber & Taylor, 1990). Nonetheless, both laboratory (Farh & Scott, 1983; Ganster, 1980; Gardner, 1986; Griffin et al., 1987; S. E. Jackson & Zedeck, 1982; Kilduff & Regan, 1988; Kim, 1980; O'Reilly & Caldwell, 1979; Terborg & Davis, 1982; Umstot, Bell, & Mitchell, 1976; Weiss & Shaw, 1979; White & Mitchell, 1979) and field (Billings, Klimoski, & Breugh, 1977; Campion & McClelland, 1991, 1993; Champoux, 1978; Frank & Hackman, 1975; Griffeth, 1985; Griffin, 1983; Lawler, Hackman, & Kaufman, 1973; Luthans, Kemmerer, Paul, & Taylor, 1987; Morgeson & Campion, 2002; Morgeson, Johnson, Campion, Medsker, & Mumford, 2006; Orpen, 1979) studies have examined how changes in job properties were perceived by incumbents.

Although many of the laboratory studies have been conducted under the auspices of testing the social information processing approach to work design, one aspect of these studies has been to manipulate task characteristics and look for corresponding changes in perceptions. Research participants are randomly assigned into one of two conditions, one with an enriched task and one with an unenriched task. Without fail, research participants identify the enriched task as higher on motivational properties. In other research, within-subject designs have been employed, where the same research participant performs both enriched and unenriched tasks (e.g., Griffin et al., 1987; Terborg & Davis, 1982; Umstot et al., 1976). Again, strong differences have been found between the task enrichment conditions. Although there are a number of concerns with this research (see Taber & Taylor, 1990), it does serve to illustrate a key point: Individuals' perceptions of work design are influenced by objective differences between tasks.

The method used in field studies has also been relatively consistent. Typically, two groups are identified, one

whose job is redesigned and the other whose job is left unchanged. Several studies have found that job incumbents perceive their jobs as having increased in motivational job properties following a redesign (Griffeth, 1985; Griffin, 1983; Luthans et al., 1987; Morgeson & Campion, 2002; Orpen, 1979). Billings et al. (1977) found that those closest to the change reported differences in task variety, importance, and interdependence, but some of these changes in perceptions actually occurred before the actual technological change occurred. This suggests that something else in the environment is partly responsible for task perceptions. Although not as uniform as laboratory research, field research also suggests that incumbent perceptions are anchored in objective features of the task.

Measurement Concerns

Common Method Variance

It has long been recognized that data collected through a single method can lead to problems with common method variance (Campbell & Fiske, 1959; Cook & Campbell, 1979; Fiske, 1982). When data are collected with the same instrument, there can be spurious covariation among responses. As a result, observed correlations reflect shared method and trait variance (Spector, 1992). Because this can inflate observed relationships between various job dimensions and outcome measures, work design research that relies on self-reported survey questionnaires has been heavily criticized (Roberts & Glick, 1981; Schwab & Cummings, 1976).

Salancik and Pfeffer (1977) suggest that consistency and priming are the underlying causal mechanisms for common method variance. Consistency refers to the tendency of individuals to remember and maintain consistency with prior responses; whereas priming refers to the influence a questionnaire can have in orienting an individual's attention to certain responses. Thus, when responding to a job design questionnaire, the respondent may attempt to maintain logical consistency between various items. For example, because there is an intuitive relationship between having job autonomy and internal work motivation, if a respondent rates autonomy as high, he or she may also feel that internal work motivation should be rated highly, if only to maintain consistency. Priming effects are likely to occur as well because most work design questionnaires collect information on a relatively narrow set of motivational job features (e.g., autonomy, variety) that, in turn, can influence or direct subsequent responding. Such psychological processes can have a profound influence on self-reported beliefs, attitudes, intentions, and behaviors

because they can result in self-generated validity (Feldman & Lynch, 1988; Tourangeau & Rasinski, 1988).

There has been a good deal of debate as to the magnitude of common method variance effects in organizational research. Some have downplayed its influence (Fried & Ferris, 1987; Spector, 1987), whereas others have been very critical (Buckley, Cote, & Comstock, 1990; Mitchell, 1985; Roberts & Glick, 1981). For example, in examining previous studies, Buckley et al. (1990) estimated mean variance due to common method variance at over 21%, with a range of 3.6% to 56.3%.

Two studies provide more direct evidence concerning the extent of common method variance in work design research. The first is a meta-analysis conducted by Cramp-ton and Wagner (1994). They investigated the degree to which self-report methods have produced percept–percept inflation in organizational behavior research. One of the broad categories they investigated was termed *job scope*, and included most of the job characteristics typically assessed in work design research (e.g., autonomy, variety, task identity, and so on). They found statistically significant levels of inflation in relationships between self-reported job scope and job satisfaction.

The second study was conducted by Glick, Jenkins, and Gupta (1986). They used structural equation modeling to investigate the relative influence of job characteristics and method effects on outcome measures. They found that the impact of method effects depended on the outcome measure they were trying to predict. For example, job characteristics accounted for two-thirds of the variance in job satisfaction when method effects are not removed, but the predicted variance dropped to 2 percent when method effects are removed. A similar, although not as great, decrease was observed for challenge satisfaction (from 77% to 15%). The ability of job characteristics to predict effort, on the other hand, actually increased when method effects were removed (from 19% to 20%). This suggests that common method variance is more likely to bias affective outcomes than behavioral outcomes.

In total, this evidence suggests that common method variance is a problem in work design research. Because of this, a variety of strategies have been used to avoid it. For example, researchers have: (a) varied survey question order (e.g., Campion, 1988; Spector & Michaels, 1983); (b) collected data from multiple sources (e.g., supervisors and incumbents; Algera, 1983; Campion & McClelland, 1991; Glick et al., 1986; Johns, 1978; Oldham et al., 1976); (c) used separate subsamples per job (Campion, 1988); (d) collected data longitudinally (Campion & McClelland, 1993); and (e) used archival measures

(e.g., objective productivity; Griffin, 1983). It would be good scientific practice to engage in some of these strategies to avoid the problems associated with common method variance.

Levels of Analysis

A final measurement concern in the work design literature concerns level of analysis issues. Although work design theorizing has typically occurred at the job level, the majority of empirical tests have occurred at the individual level (see Morgeson & Humphrey, 2006, for an exception). Thus, in many instances, the level of measurement and the level of theory are different. By itself, this is not necessarily a problem. Differences in level of measurement and level of theory are common, and choosing a level for empirical testing should be guided by one's theoretical model (Klein, Dansereau, & Hall, 1994; Morgeson & Hofmann, 1999). Individuals could be considered informants about their jobs and therefore the best judge of a job's properties.

When data are analyzed at the individual level, however, one is dealing with the perceptions of incumbents, and it is unclear how much these perceptions agree with the perceptions of other incumbents in the same job (the convergence research reviewed above did not examine within-job convergence). Although some degree of variability would be expected, work design theories rely on the assumption that there is a high level of agreement among incumbents. There is reason to believe there is a lack of convergence in a large amount of work design research.

For example, much empirical work design research has been conducted with a single job title. Given that incumbents are performing the same job, one would expect there to be little variability in reports about various job characteristics. If there is no variance in job characteristics, then it is statistically impossible for these characteristics to be significantly related to any other variable. But this research typically finds significant relationships with a host of measures, including satisfaction and motivation. This suggests that there is variance within a job and this within-job variability is responsible for many significant results. Because this is inconsistent with work design theory, caution should be exercised in interpreting findings based on a single job.

It is likely there are both job-level and individual-level influences on work design outcomes. For example, workers will perceive the amount of autonomy designed into the job itself similarly, but some workers are also likely to be given greater discretion depending on their relationship with their supervisor. Thus, the amount of autonomy

reported by an incumbent will be a function of both individual and job-level factors. Existing work design theory, however, does not clearly identify individual versus job-level sources of variation in job design.

Another level of analysis issue concerns when data should be aggregated from the individual to the job level. First, theorizing should refer to the job, not the individual. Most work design theory does refer to the job (or team) level. Second, the measures should reference the job, not the individual (Morgeson & Hofmann, 1999). This will indicate to the respondent that ratings should be made about the job, not individual reactions to the job. Third, empirical support for aggregation to the job level should always be provided. This would include the calculation of interrater reliability via the intraclass correlation (Bartko, 1976) as well as an examination of interrater agreement (James, Demaree, & Wolf, 1984). If the r_{wg} statistic is used (James et al., 1984), a normal or negatively skewed distribution should be assumed, not a rectangular distribution.

MEDIATING MECHANISMS IN WORK DESIGN

A key conceptual question in work design concerns the underlying psychological mechanisms through which work design influences affective and behavioral outcomes. Hackman and Lawler (1971) suggested that jobs must (a) allow workers to feel responsible for a meaningful and identifiable part of the work; (b) provide outcomes that are intrinsically meaningful; and (c) provide feedback about performance success. Subsequent work by Hackman and Oldham (1976, pp. 256–257) referred to these three critical psychological states as experienced meaningfulness, experienced responsibility, and knowledge of results. They suggested that changes in work design influenced affective and behavioral outcomes because they altered these critical psychological states. Early evidence exploring the intervening role played by the psychological states was mixed (Fried & Ferris, 1987; Johns, Xie, & Fang, 1992; Oldham, 1996). For example Johns, Xie, and Fang (1992) found that of the three psychological states, experienced meaningfulness captured the majority of the mediation effects. Similar results were obtained in Humphrey et al.'s (2007) meta-analytic test of the job characteristics–critical psychological states–outcomes mediation model.

Two mediating mechanisms that follow from experienced meaningfulness are perceived social impact and social worth. Drawing from earlier work by Hackman (1990) and Hackman and Oldham (1980) that suggested

that contact with clients could impact employee outcomes, Grant and colleagues have explored the role of perceived social impact (i.e., “the degree to which employees feel that their actions benefit other people”; Grant, 2008a, p. 110) as a mediator between work design characteristics and important organizational outcomes. Specifically, they have looked at the mediating role perceived social impact plays between the task significance–job performance relationship (Grant, 2008a) and between the contact with beneficiaries–persistence behavior relationship (Grant et al., 2007). For example, in a sample of university fundraisers, Grant et al. (2007) found that contact with beneficiaries increased employee persistence (i.e., the number of fundraising calls made) by increasing employee perceptions of perceived social impact. Similarly, work by Grant and Gino (2010) has examined the intervening role that social worth (i.e., “the degree to which employees feel that their contributions are valued by other people”; Grant, 2008a, p. 110) plays in the relationship between contact with beneficiaries and prosocial behaviors. Across two laboratory studies, they found that workers who received a written expression of thanks were more likely to assist the beneficiary that wrote the letter as well as other beneficiaries. Using a field experiment, they also found that when managers expressed gratitude, university fundraisers made more fundraising calls. Together these results suggest that designing or redesigning jobs to include interactions with others may help expose workers to their beneficiaries, increasing feelings that their actions matter in other people's lives. This research is important because it offers empirical evidence in support of new meditational mechanisms.

Morgeson and Campion (2003) suggested that psychological empowerment might provide a more parsimonious description of the motivational benefits of enlarged work. Empowerment has been described as an active motivational state characterized by four distinct cognitions: (a) meaning, (b) competence, (c) self-determination, and (d) impact (Spreitzer, 1995). Thus, Morgeson and Campion (2003) argued that many of the motivational work characteristics highlighted earlier would seem to be logically related to the experience of empowerment (Gagne, Senecal, & Koestner, 1997; Kraimer, Seibert, & Liden, 1999).

The mediating role of empowerment was examined by Liden, Wayne, and Sparrowe (2000) in a study that assessed the extent to which it mediated the relationship between motivational job characteristics, leadership, and quality of coworker relationships and work outcomes. Although not solely testing work design factors, Liden et al.

(2000) found that some of the empowerment dimensions partially mediated the relationship between work design and satisfaction, commitment, and job performance. Other research has looked at the link between psychological empowerment and several attitudinal and behavior outcomes, including job satisfaction, intrinsic motivation, commitment, job performance and productivity, and proactivity and innovation (Gagne et al., 1997; Kirkman & Rosen, 1999; Kirkman, Rosen, Tesluk, & Gibson, 2004; Liden et al., 2000; Spreitzer, 1995).

There are, however, potential discriminant validity problems with the notion that work design increases psychological empowerment. This is due to the fact that at least one popular measure of empowerment utilizes the job characteristic of autonomy as an indicator of empowerment (labeled “self-determination”; see Spreitzer, 1995). Thus, at some level it is not clear the extent to which motivational features of work (e.g., autonomy) are separable from the psychological experience of work.

Self-efficacy is also a potentially important mediating mechanism that has received recent attention. Parker and Ohly (2008) suggest that enriched jobs help promote self-efficacy by increasing one’s enactive mastery experiences (i.e., repeated performance success) and perceived controllability over one’s tasks. This is supported by recent evidence that shows that job enrichment is indeed related to self-efficacy (Axtell & Parker, 2003; Burr & Cordery, 2001; Parker, 1998; Sprier & Frese, 1997). In a series of studies, Parker and colleagues (Griffin, Neal, & Parker, 2007; Parker, Williams, & Turner, 2006) have looked at a more specific type of self-efficacy, mainly role-breadth self-efficacy (i.e., “feeling capable of taking on a more broad and proactive set of responsibilities”; Parker & Ohly, 2008, p. 432). They argue that autonomy increases one’s sense of role-breadth self-efficacy, which in turn leads to more proactive behaviors. In early work, Parker (1998) found that across two field studies, autonomy was an important facilitator of role-breadth efficacy. Later, in a sample of U.K. wire makers, Parker et al. (2006) found that workers higher in role-breadth self-efficacy were more likely to engage in proactive work behaviors (e.g., proactive idea implementation and proactive problem solving).

All of the preceding formulations have relied on motivational explanations for how work design impacts affective and behavioral outcomes. In other words, they suggest that work design enhances work satisfaction and job performance by encouraging greater effort. However, there are other potential mediating mechanisms that are worth mentioning. One such mediator is the speed at which an individual can respond to problems. This idea of “quick

response” (Parker & Wall, 1998, 2001; Parker et al., 2001; Wall & Martin, 1987) suggests that when individuals have control over the decisions they make on the job, they will be able to quickly, effectively, and efficiently handle problems that arise (Morgeson & Humphrey, 2008).

Wall and Jackson (1995) offer a knowledge-based explanation. They suggest that changes in work design may improve organizational outcomes because increases in such things as autonomy not only tap into the existing knowledge of the workforce but also allow further learning on the job. In essence, there are logistical advantages associated with greater job control. If workers have the knowledge and authority to deal with problems as they arise, they may be able to respond more quickly to the problem. In addition, greater job control promotes workers’ understanding of the work system, thereby enhancing learning. If they learn more about the system, they are better able to anticipate and avoid problems (Wall et al., 1992). Similarly, autonomy can facilitate learning and development, and this increased knowledge can have beneficial effects on job performance (Parker, Wall, & Jackson, 1997).

Such a knowledge-based explanation is given further support in the research of Campion and McClelland (1993). They distinguished between task enlargement and knowledge enlargement and examined the effects of both on a variety of outcomes. Task enlargement involved adding requirements for doing other tasks on the same product, whereas knowledge enlargement involved adding requirements to the job for understanding procedures or rules relating to different products. They found that simply increasing the tasks resulted in a variety of negative outcomes over time (e.g., more mental overload, lower job efficiency). Increasing the knowledge component of the work, however, resulted primarily in benefits over time (e.g., satisfaction, less mental overload, better customer service). This converges with research that suggests that mental demands account for the effects of motivational job design (Campion, 1988; Campion & Thayer, 1985). But as Morgeson and Humphrey (2008) highlight, however, learning alone may not be sufficient, noting that it is important for workers to make use of the knowledge and skills that they develop. As such, they propose exploring the role of skill utilization (i.e., “the extent to which individual and team skills are effectively utilized”; Morgeson & Humphrey, 2008, p. 75). They suggest that when work is designed to tap into existing knowledge and skill bases (e.g., by enhancing autonomy), then one can also tap into formal and tacit knowledge and skills (Morgeson et al., 2006; Parker et al., 2001; Wall & Jackson, 1995).

Recently, researchers have called more attention to the role that self-regulation may play in relation to work design (Parker & Ohly, 2008). Morgeson and Humphrey (2008) note that self-regulation theories may serve as a way to integrate prior work on many of the mediating mechanisms discussed above. Similarly, Parker and Ohly (2008) highlight the role of motivational processes, including goal generation and goal striving in their extended framework. One specific mediating mechanism, promotion and prevention focus, seems particularly promising. Parker and Ohly (2008) suggest that enriched jobs will help stimulate a promotion focus (i.e., focus on advancement and growth) instead of a prevention focus (i.e., focus on security, safety, and responsibility). Based on Meyer, Becker, and Vandenberghe's (2004) integrated model of commitment and motivation, which looks at both internal (needs, values, and personal dispositions) and external (rewards, punishments) forces of behavior, Parker and Ohly (2008) propose that narrow job designs with low autonomy will lead to a sense of external control, whereas enriched jobs will lead to feelings of internal control, which is related to a promotion focus. In addition, both promotion and prevention focus have been shown to influence different behaviors, with promotion focus influencing creative processes (Friedman & Förster, 2001, 2005). In contrast, researchers have suggested that prevention focus is associated with satisfying behaviors that are limited in scope. Thus, not surprisingly Wallace and Chen (2006) found that prevention focus was negatively related to productivity (i.e., work quantity and speed). However, it is important to highlight that prevention focus was an important predictor of safety performance (i.e., adherence to rules and regulations), whereas promotion focus was negatively related. Thus, although more evidence is needed in this area, self-regulation theories seem to provide an additional lens through which we can look at work design and its impact on various outcomes.

OUTCOMES OF WORK DESIGN

In their meta-analysis, Humphrey et al. (2007) look at an extended list of work design outcomes ranging from role ambiguity to organizational commitment. Using this as a framework, we incorporate additional outcomes identified in Morgeson and Humphrey's (2008) expanded discussion of work outcomes. The result is the following four domains of work design outcomes: attitudinal, behavioral, cognitive, and well-being. Given space constraints, we discuss only a few of the categories within each of these

larger outcome domains (Figure 20.1 provides a more extensive list of the categories within each of the four outcome domains). As noted by Morgeson and Humphrey (2008; p. 47), "To begin to understand work design, it is important to articulate the different outcomes that may result from different work design features." With this in mind, we proceed with our discussion on work design outcomes.

Attitudinal Outcomes

Attitudinal outcomes center on one's feelings toward the job, team, or organization. Researchers have looked at numerous attitudinal outcomes such as satisfaction (including job, supervisor, coworker, team, growth, and promotion satisfaction; Hackman & Oldham, 1976; Warr, Cook, & Wall, 1979), team viability (Hackman, 1987; Sundstrom, DeMeuse, & Futrell, 1990), organizational commitment (Meyer, Stanley, Herscovitch, & Topolnysky, 2002), job involvement (Brown, 1996), and internal work motivation (Ryan & Deci, 2001).

Humphrey et al.'s (2007) meta-analysis shed light on the relationship between various work characteristics and attitudinal outcomes. For example, they found that autonomy, skill variety, task significance, task identity, and feedback from the job were all related to multiple facets of satisfaction. Specifically, they found that these five characteristics were related to job satisfaction (mean $p = 0.41$), supervisor satisfaction (mean $p = 0.30$), compensation satisfaction (mean $p = 0.19$), growth satisfaction (mean $p = 0.55$) and promotion satisfaction (mean $p = 0.21$). Autonomy demonstrated the strongest relationship with each of the satisfaction outcomes (with the exception of promotion satisfaction, in this case feedback from the job had the strongest relationship). These five characteristics were also related to organizational commitment, job involvement, and internal work motivation (mean of $p = 0.34$, $p = 0.29$, and $p = 0.39$, respectively). They also found that task variety was related to job satisfaction, supervisor satisfaction, compensation satisfaction, and promotion satisfaction (range of $p = 0.19$ to 0.46). Both information processing and job complexity were related to job satisfaction ($p = 0.38$ and $p = 0.37$, respectively). Job complexity was also related to job involvement ($p = 0.24$). In addition, social support, interdependence, interaction outside the organization, and feedback from others had a moderate relationship with job satisfaction (mean $p = 0.36$). Interestingly, social support was highly related to organizational commitment ($p = 0.77$), suggesting that work design efforts aimed at increasing an employee's

commitment to the organization may want to focus on this component of the social environment.

Behavioral Outcomes

Behavioral outcomes focus on the actions of workers. Although traditionally researchers have concentrated on the quantity (i.e., amount) and quality (i.e., accuracy, innovation, or customer service) of job performance, there are numerous other ways in which work design can impact workers' behaviors, including innovation (Axtell, Holman, Unsworth, Wall, Waterson, & Harrington, 2000), creativity (Shalley, Zhou, & Oldham, 2004), citizenship behaviors, counterproductive behaviors, absenteeism, and turnover.

For example, Oldham and Cummings (1996) found that employees who worked in enriched jobs were more likely to have higher ratings of creativity, produce more patents, and offer more suggestions. Elsbach and Hargadon (2006) took a unique perspective, suggesting that organizations use a new framework of "workday design" to enhance employee creativity. They argue that organizations should focus on designing an entire workday rather than designing a particular work task. Specifically, they suggest that to enhance creativity among chronically overworked professionals, organizations should design a workday to include a mix of cognitively challenging work as well as mindless work (i.e., work that is low in both cognitive difficulty and performance pressure). Their argument rests on the idea that by alternating between challenging tasks and mindless tasks, employees can achieve a balance of pressure and relaxation that may help them achieve greater creativity and lower stress.

An additional behavioral outcome that has received increasing research attention of late is that of proactivity. Although different construct labels have been used by different research teams, each focuses on the dynamic role that employees play in altering and enacting their own jobs. This focus on proactivity can be found in Wrzesniewski and Dutton's (2001) work on job crafting. In their influential article, the authors define job crafting as "the physical and cognitive changes individuals make in the task or relational boundaries of their work" (p. 179). Changes can include altering the number and types of tasks (Morgeson et al., 2005), reframing views of one's tasks, or altering how and whom one interacts and communicates with at work. Central to their model is the idea that employees engage in job crafting in order to instill a greater sense of control, meaning, positive identities, and interpersonal connection into their work. As an example,

the authors describe how a group of hospital cleaners may craft their jobs to include interacting with and caring for patients and family members despite it not being a part of their formal job description. Finally, Rousseau, Ho, and Greenberg (2006) have presented the idea of "i-deals," in which supervisors and employees agree to a unique job arrangement that differs from those given to other employees. Taken together, these different perspectives clearly mark a move away from the idea of jobs as static in nature, and instead recognize the critical role that employees play as "shapers" of their own jobs.

Meta-analytic evidence suggests that work characteristics do in fact impact employee behaviors. Humphrey et al. (2007) found that autonomy was related to objective performance ($p = 0.17$), and that autonomy, task identity, task significance, and feedback from the job were all related to subjective performance (mean $p = 0.18$). Task variety was also related to subjective performance ($p = 0.23$) as were the social characteristics of interdependence and feedback from others ($p = 0.18$ and $p = 0.28$, respectively). In addition, autonomy, task identity, feedback from the job, and social support were all negatively and significantly related to absenteeism (range of $p = -0.09$ to -0.15). Surprisingly, they found no studies that looked at the relationship between social characteristics and objective performance. Future research may want to explore this gap to help us gain a better understanding of this relationship.

Cognitive Outcomes

Cognitive outcomes consist of two components: (a) one's thoughts about one's job, and (b) the developmental outcomes of one's work. Within this broader category, we see research that has looked at learning and development (Edmondson, Bohmer, & Pisano, 2001), role perceptions (including role ambiguity, role conflict, role breadth self-efficacy, and flexible role orientation; Rizzo, House, & Lirtzman, 1970; Parker, 1998; Parker et al., 1997), turnover intentions (Lee & Mitchell, 1994), and team identification (Van der Vegt & Bunderson, 2005).

Based on Humphrey et al.'s (2007) meta-analysis, we have a clearer picture of how different work characteristics relate to some of the cognitive outcomes outlined above. For example, they found that autonomy was related to both role ambiguity and role conflict ($p = -0.23$ and $p = -0.17$, respectively). Similar results were found for feedback from the job, which demonstrated a strong negative relationship with both role ambiguity and role conflict ($p = -0.43$ and $p = -0.32$, respectively). One interesting finding was that none of the traditionally motivating

work characteristics (i.e., autonomy, skill variety, task significance, task identity, and feedback from the job) were related to turnover intentions. However, the opposite was true for social characteristics. Interdependence, feedback from others, and social support were found to have a negative relationship with turnover intentions (range of $p = -0.17$ to $p = -0.34$).

Well-Being Outcomes

Well-being outcomes include both physiological as well as psychological reactions to the job. This set of outcomes includes stress (e.g., Sprigg, Stride, Wall, Holman, & Smith, 2007), anxiety (e.g., Sprigg & Jackson, 2006), engagement (e.g., Christian et al., 2011), burnout or exhaustion (e.g., Bakker et al., 2005; Le Blanc, Hox, Schaufeli, Taris, & Peeters, 2007), overload, work/family issues (e.g., Valcour, 2007), occupational safety (e.g., Barling, Kelloway, & Iverson, 2003), and physical health outcomes (e.g., Aboa-Éboulé et al., 2007).

One well-being outcome that seems particularly important is that of safety outcomes. Given the extreme financial and human costs associated with workplace fatalities, injuries, and illnesses, work design researchers should look at how jobs can be designed or redesigned to increase workplace safety. For example, Barling et al. (2003) showed high-quality jobs (i.e., jobs that are composed of extensive training, variety, and autonomy) affect occupational injuries. Using data from the Australian Workplace Industrial Relations Survey, they found in a sample of 16,466 employees that high-quality jobs had a direct effect on workplace injuries and an indirect effect through the mediating influence of job satisfaction. More recently, Nahrgang et al. (2011) have reasserted the importance of looking at safety outcomes in their meta-analysis that looks at the role of job demands and resources. Interestingly, they found that job demands (i.e., risks and hazards, physical demands, complexity) and job resources (i.e., knowledge, autonomy, supportive environment) operate through a health impairment process and a motivational process to influence safety outcomes. In particular they found that job resources were negatively related to burnout, and that burnout was negatively related to safe work behaviors. They also found that job demands had a negative relationship with engagement, and that engagement was in turn positively related to safe work behaviors.

Humphrey et al. (2007) highlight several interesting meta-analytic findings in regard to well-being outcomes that are worth mentioning. First, although autonomy and feedback from the job were both negatively related to

anxiety ($p = -0.10$ and $p = -0.32$ respectively) and stress ($p = -0.23$ and $p = -0.21$, respectively), neither was related to overload. However, in line with arguments posed by Morgeson and Humphrey (2008), task variety, task significance, and information processing were each positively related to overload ($p = 0.38$, $p = 0.38$, and $p = 0.58$, respectively). Second, four characteristics (i.e., autonomy, skill variety, task significance, and task identity) were negatively related to burnout/exhaustion (mean $p = -0.26$), suggesting that additional research should look at that the Job Demands–Resources model (Bakker & Demerouti, 2007; Demerouti et al., 2001) as a way to explore this link. Third, work conditions explained an incremental 16% of the variance in stress, more than the five motivational characteristics or the social characteristics. This finding highlights the significance of work conditions specifically and the larger organizational context more generally as impacting important well-being outcomes.

Summary

Work design research has moved beyond the traditional focus on attitudinal and behavioral outcomes, to a focus that now recognizes work designs' impact on both cognitive and well-being outcomes. Meta-analytic results (Humphrey et al., 2007) have given us a greater understanding of the relationship between numerous work characteristics and outcomes. These results provide evidence for the importance of looking at an extended list of work characteristics given the different relationships to various attitudinal, behavioral, cognitive, and well-being outcomes. These findings also point to potential areas of future research given that many of the relationships have yet to be explored empirically.

WORK REDESIGN INTERVENTIONS

A large amount of work design research has been cross-sectional in nature. This is problematic because it severely limits the kinds of causal conclusions one can reach. Coupled with the fact that much of the cross-sectional research is plagued with common method bias, research on work redesign interventions offers the opportunity to determine how actual changes to jobs impact worker outcomes. As such, work redesign research allows us to have a more veridical understanding of the work design phenomena discussed throughout this chapter.

Many studies suggest that when interventions are guided by motivational approaches, job satisfaction increases.

Positive results have been found for a variety of different jobs, including telephone service representatives, key punchers, clerks, and operators (Ford, 1969); insurance key punchers (Hackman, Oldham, Janson, & Purdy, 1975); government clerks (Graen, Scandura, & Graen, 1986; Orpen, 1979); university receptionists (Griffeth, 1985); garment manufacturing jobs (Coch & French, 1948); telephone installers, connectors, and engineers (Ford, 1969); product inspectors (Mather & Overbagh, 1971); technicians, salespersons, engineers, and supervisors (Paul, Robertson, & Herzberg, 1968); clinical research information systems workers (Morgeson & Campion, 2002); machine shop workers (Griffin, 1983); insurance paperwork processors (Campion & McClelland, 1991, 1993); and blue-collar petrochemical jobs (Ondrack & Evans, 1987). These positive results, however, should be tempered by other research that has been less than supportive (Bishop & Hill, 1971; Frank & Hackman, 1975; Griffin, 1991; Lawler et al., 1973; Locke, Sirota, & Wolfson, 1976; Luthans et al., 1987).

Other change efforts not guided by the motivational approach have also been studied. These changes have typically occurred when new technology, operating procedures, or work locations are implemented. As one might imagine, these types of changes have had a number of different effects on employee outcomes. For example, Billings et al. (1977) examined the implications of a change from batch to mass production in the dietary department of a hospital. Although decreases in satisfaction and attendance were expected because of negative changes to work characteristics, none were found. Hackman et al. (1978) investigated the installation of office automation. They found that when motivational job characteristics were increased, internal work motivation (i.e., positive internal feelings when performing effectively) and satisfaction increased. When motivational job characteristics were decreased, internal work motivation and satisfaction decreased.

In the Oldham and Brass (1979) study mentioned earlier, although there were no objective changes to the work, perceptions of job characteristics changed and satisfaction and motivation decreased. Wall, Clegg, Davies, Kemp, and Mueller (1987) studied the shift from manual to automated assembly. They found little evidence that increased automation results in deskilling of work. Wall, Corbett, Martin, Clegg, and Jackson (1990) examined the impact of increased operator control. They found that increased control resulted in reduced levels of downtime, particularly for high-variance technologies. Increases in job satisfaction and reductions in job pressure were also observed.

Morgeson and Campion (2002) conducted a longitudinal quasi-experiment in which jobs were differentially changed in terms of their motivational and mechanistic properties. They found that satisfaction, efficiency, training requirements, and work simplicity could be differentially affected, depending on the changes made to the jobs.

Finally, drawing from an important conceptual article (Grant, 2007), in a series of field and lab studies Grant and colleagues (Grant 2008a, 2008b; Grant et al., 2007) have explored how social elements of the job can be structured to enhance employee prosocial motivation. In the first of these studies, Grant et al. (2007) looked at this relationship in a longitudinal field experiment of university fund-raising call center employees. They found that workers who had contact with a scholarship recipient (in order to learn how the recipient benefited from his or her scholarship) spent more time making phone calls and raised more money. This is in contrast to callers in two control groups, who showed no significant changes. Similar results were found in a field experiment of lifeguards. Grant (2008a) found that lifeguards who read stories about how their work could benefit swimmers showed a significant increase in job dedication and helping behavior. Lifeguards in the control condition, who read stories about the potential personal benefits of their work, did not show an increase in either area.

INDIVIDUAL DIFFERENCES IN WORK DESIGN

Individuals differ in terms of the attitudes and beliefs they hold, what they value, and how they respond to their environment. Research has investigated how these individual differences may influence responses to work design.

Early Research

Turner and Lawrence (1965) initiated research into individual differences. They found evidence that urban/rural background moderated the relationship between job characteristics and satisfaction, with those from rural backgrounds responding more positively to enriched work. At about the same time, other researchers (Blood & Hulin, 1967; Hulin & Blood, 1968) investigated "alienation from middle-class norms" and found limited evidence for the moderator among blue-collar respondents. Others also found significant moderating effects for job involvement (Ruh, White, & Wood, 1975) and need for achievement (Steers, 1975). Additional research on such things as community size (Shepard, 1970) and Protestant Work Ethic

(Stone, 1975, 1976), however, found little to no evidence (White, 1978).

Growth Need Strength

The most commonly studied moderator of the work design–work outcome relationship is Growth Need Strength (GNS). GNS is the preference or need individuals have for stimulating and challenging work. The basic premise is that motivation and satisfaction will result from a fit between the task characteristics and the needs of the employees, where the relationship between motivating job design and job satisfaction will be strongest for high-GNS individuals, although the validity of such need-based explanations has been questioned (Salancik & Pfeffer, 1977).

Meta-analytic studies have summarized this research and have reached optimistic conclusions about the moderating role of GNS. For example, Fried and Ferris (1987) suggested that GNS moderated the relationship between motivational job design and job performance, although they found only five studies had actually examined this relationship. After conducting a meta-analysis of 28 studies, Loher et al. (1985) concluded that GNS was useful as a moderating variable of the job design–job satisfaction relationship. Unfortunately, this conclusion was based on comparing correlations for high- and low-GNS workers. As we have come to understand, comparing subgroup correlations is analytically inferior to more sophisticated regression techniques (Stone & Hollenbeck, 1984).

More recent research, however, has reached less optimistic conclusions. Using a large sample of jobs and respondents (876 jobs, 6,405 total respondents), Tieg, Tetrick, and Fried (1992) comprehensively tested the moderating influence of GNS and context satisfaction. They found virtually no support for any moderating effect. Similarly, Rentsch and Steel (1998) found no moderating effect of competence or need for achievement, suggesting that growth needs do not act as moderators.

Additional Individual Differences

The mixed evidence in support of GNS as a moderator has led to the consideration of other individual differences. For example, Morgeson and Campion (2003) suggested that an employee's ability level may influence their reactions to job redesign efforts. They suggest that if the cognitive ability required by the job is beyond that which the individuals possess, they may react less positively to the change. Schneider et al. (1982) and Dunham (1977) found

significant relationships between motivational characteristics of jobs and various ability requirements. From the multidisciplinary perspective, Campion (1989) found that motivational job design has a positive relationship with a wide range of mental ability requirements and that jobs designed from a mechanistic or a perceptual perspective were negatively related to mental ability requirements. More recently, Morgeson and Humphrey (2006) found that knowledge characteristics (e.g., job complexity, information processing, and problem solving) were all related to an underlying cognitive ability component. This suggests that workers high in cognitive ability would perform better in jobs with high levels of these knowledge characteristics. In addition, Morgeson and Humphrey (2008) propose that jobs high in skill variety or specialization will also be best performed by individuals with high cognitive abilities. Although it remains an important research question, there is a dearth of research specifically investigating the moderating role of employee abilities (Fried & Ferris, 1987).

Despite the dominance of the Big Five personality traits across other research domains it has remained largely absent from the work design literature. Morgeson and Humphrey (2008) called attention to conscientiousness, agreeableness, and extraversion as potential moderators, suggesting that these individual differences would be especially important in jobs with high social or interpersonal demands. Recent empirical results would seem to support their view. In a sample of new fundraisers, Grant (2008a) found that conscientiousness moderated the relationship between task significance and performance such that the relationship was stronger for individuals high in conscientiousness. Additional research exploring the role of other Big Five traits is needed to help explicate the moderating role they might play.

Research has also examined whether negative affectivity (the stable tendency to experience negative emotions) and positive affectivity (the stable tendency to experience positive emotions) are related to incumbent perceptions of job characteristics. This research has been prompted by suggestions that negative affectivity may seriously bias self-report measures (Brief, Burke, George, Robinson, & Webster, 1988; Burke, Brief, & George, 1993). In directly testing the impact of negative and positive affectivity on job characteristics ratings, both Munz, Huelsman, Konold, and McKinney (1996) and Spector et al. (1999) found little evidence that negative affect had any impact on ratings. More recently, Fortunato and Stone-Romero (2001) found that positive affect, but not negative affect, moderated the relationship between task enrichment and task

perceptions. They suggested that these individual dispositions may indeed play a moderating role on perceptions of situational characteristics that are ambiguous.

Another potentially critical individual difference discussed in recent work is psychological flexibility. Psychological flexibility represents an ability to focus on the present moment and to persist with or change one's behavior in the pursuit of goals and values (Bond, Flaxman, & Bunce, 2008). Core to the idea of psychological flexibility is that individuals deliberately assess their internal experiences in a mindful manner (i.e., nonjudgmental and noncontrolling manner; Hayes, Luoma, Bond, Masuda, & Lillis, 2006), redirecting their attentional resources to that of the present moment. Thus, they are more able to effectively notice and respond to goal-associated opportunities that exist in the present situation (Bond et al., 2008), making it an important individual difference for a variety of outcomes, including job performance, motivation, absenteeism, and well-being (Bond & Hayes, 2002). In their recent quasi-experiment in a call center, Bond et al. (2008) found that psychological flexibility moderated the effects of a control-enhancing work redesign intervention. Compared to a control group, workers who underwent the intervention showed improvements in terms of mental health and absenteeism, such that this relationship was stronger for individuals high in psychological flexibility. Results indicated that these effects were mediated through enhanced job control.

In a somewhat related vein, another individual difference construct that could be potentially useful to explore in work design research is temporal focus. Temporal focus is defined as the extent to which an individual devotes his or her attention to perceptions of the past, present, and future (Bluedorn, 2002). As noted by Shipp, Edwards, and Lambert (2009), temporal focus is an important construct because "thinking about the past, present, and future affects current attitudes, decisions, and behaviors" (p. 1). This is supported by evidence from goal-setting, motivation, performance (Bandura, 2001; Cottle, 1976; Fried & Slowik, 2004; Nuttin, 1985), and affect (Wilson & Ross, 2003) research. There is recent evidence that suggests that individuals high in a given temporal focus may experience jobs differently. Shipp et al. (2009) found that when individuals were high in future temporal focus (i.e., a tendency to think about things in the future) their current job satisfaction was positively related to the anticipated levels of job characteristics (i.e., autonomy, recognition, and opportunities for advancement). The opposite was true when future focus was low. Similar results were shown for organizational commitment, such that organizational

commitment was positively related to anticipated autonomy when future focus was high, but not when future focus was low. Interestingly, they found that when past temporal focus (i.e., a tendency for individuals to focus on the past) was high, turnover intent was positively related to past levels of autonomy, recognition, opportunities for development, and pay. Together, these results suggest that the extent to which past and future job characteristics influence attitudinal outcomes depends on the degree to which individuals focus on past, present, or future time periods. For example, focusing on past job characteristics could affect current job satisfaction in ways that mimic the effects of current job characteristics such that feelings associated with those past characteristics are carried over into current job satisfaction. Although this represents a first step toward looking at the role of temporal focus, the results do seem to suggest that one's perception about the past, present, and future may impact the way one experiences current job characteristics.

Summary

After a long period where GNS was the primary individual difference studied, research has begun to explore other potentially important individual differences. We are encouraged by this trend and look forward to future research that enhances our understanding of how individual differences influence reactions to different features of work. Yet, any future research should be guided by three observations about past research and the practical implications of any differences found. First, much of the early work design research that found evidence for moderation employed inappropriate analytic techniques. Subgroup analyses were commonly conducted, where samples were divided into the top and bottom thirds on the measure of interest (e.g., GNS). Correlations between job design measures and outcomes for each group were then compared and differences in the magnitude of these correlations were offered as evidence for moderation. It is doubtful that more rigorous analytic techniques (i.e., moderated multiple regression) would yield the same conclusions.

Second, in most instances where jobs are being designed for multiple employees, it is best to design jobs in accordance with the average or typical employee. If jobs are tailored to the individual preferences of each current incumbent, the jobs may not be well suited for future incumbents who might possess different preferences. Furthermore, redesigning the job for each new employee is impractical, and predicting the preferences of future employees is likely to become more difficult with changes in labor market demographics.

Third, the relationships between the job design models and their outcomes tend to be positive for all employees, even if they differ in magnitude between employees. For example, although some employees may respond more positively to the motivational approach than others, the relationship is rarely negative. That is, typically all employees respond positively to motivating work, but some respond more positively than others (White, 1978). Research on GNS is a good illustration. Even those employees low in GNS showed small increases in job satisfaction in response to motivating job characteristics (Loher et al., 1985). In addition, there is evidence that people generally prefer work that is designed to be motivating. Campion and McClelland (1991) found that individuals generally preferred jobs designed from the motivational perspective and not the perceptual perspective (i.e., job design that seeks to reduce the information processing requirements of work), but were ambivalent about jobs designed from the mechanistic or biological perspective.

AN INTEGRATED WORK DESIGN FRAMEWORK

As this chapter has illustrated, a wide range of issues have been investigated in work design. Although informative, there exists no overall framework integrating this research. Figure 20.1 provides an integrative framework that summarizes the issues that have been investigated in the literature. It is not a formal model in the sense that it provides testable hypotheses. Instead, it is a heuristic device that quickly and economically conveys the major work design factors that have been investigated.

Contextual Influences

Contextual influences define the left-most side of the model. These include the range of social factors identified in the testing of social information processing theory, such as coworker job satisfaction and job complexity, as well as leader behavior. Although these social influences have commonly been viewed as biasing factors in the perception of work characteristics, they may instead represent important inputs into the social environment of work.

Structural influences such as organizational structure, technology, and the physical environment are the other main types of contextual influence. These factors have been much less widely studied, but they are likely to serve as important boundary conditions for the design of work. For example, the range of possible work design choices

will be limited by the formalization and centralization of the organization or the primary technology that is used. These structural influences do not dictate the design of work; they just place important limits on it.

Characteristics of Work

Characteristics of work constitute the next major element in the model. The bulk of evidence from the research conducted in the work design literature and elsewhere suggests that work can be divided into (a) task, (b) knowledge, (c) social, and (d) contextual domains. The task domain reflects the range of task characteristics commonly investigated (e.g., variety, autonomy). The knowledge domain reflects the more recently identified characteristics of mental demands, types of job control, specialization, and work responsibility. In essence, increases in these work features tend to make work more complex to perform, thereby increasing the mental demands placed on the worker.

The social domain has historically received less research attention than the task or knowledge domain, but recent research has begun to address this gap. More work is clearly needed into other features of the social environment, such as how feedback from others and social support relate to important work design outcomes. The contextual domain has all but been ignored in contemporary work design research (but has a strong tradition in other domains). This is unfortunate, because such things as physical activity, working conditions, technology used, and ergonomic design have been shown to have important relationships with worker outcomes. Clearly, more research is needed to integrate contextual features into work design research.

Mediating Mechanisms

There is considerable evidence that the aforementioned characteristics of work are directly related to outcome measures. There is at least some reason to believe, however, that several factors mediate between work characteristics and outcomes. The critical psychological states outlined by Hackman and Oldham (1975) have received only limited support as a mediating mechanism. Psychological empowerment has been forwarded as another possible mediating mechanism, and appears to offer a more parsimonious account of the motivational benefits of enriched work.

Knowledge-based explanations for the benefits of enriched work have only recently been forwarded, but they

provide a compelling alternative perspective. It may be that positive outcomes (particularly behavioral outcomes) are simply due to increased knowledge of the organizational system and the ability to anticipate and respond to problems more quickly. Although not discussed in the literature, two other knowledge-level mechanisms become apparent. First, jobs might be designed or redesigned to better take advantage of the skills possessed by employees. Second, work complexity is directly related to the information processing demands of the work. It may be that positive relationships between work characteristics and behavioral outcomes are due to their shared relationship with mental ability.

Outcomes

A host of attitudinal, behavioral, cognitive, and well-being outcomes have been investigated in the work design literature. Such psychological outcomes as job satisfaction and internal work motivation have been very heavily researched, whereas mental overload and underload have received less research attention. Relatively few of the behavioral outcomes have been studied, and only absenteeism has been found to be a consistent work design outcome. It seems clear that work design has some fairly predictable human resource outcomes, with skill requirements, training demands, and compensation levels all being related to different forms of work design.

TENSIONS IN WORK DESIGN

Although a great deal of work design research has been conducted over the past 50 years, many issues still remain unresolved. One issue that may pose a challenge to job design and redesign efforts involves how specific configurations of work characteristics can produce different outcomes (Morgeson & Humphrey, 2008). When work is designed or redesigned, there are inherent tensions between different work design approaches (Campion, Mumford, Morgeson, & Nahrgang, 2005). For example, changes aimed at increasing the satisfying aspects of work often make it less efficient. Similarly, changes aimed at making work more efficient generally make it less satisfying and motivating (Campion, 1988; Campion & Thayer, 1985). Until recently, it was thought that these kinds of tradeoffs were impossible to resolve (Campion & McClelland, 1993). Recent research suggests that it may be possible to eliminate (or at least minimize) these tradeoffs (Edwards et al., 2000; Morgeson & Campion, 2002).

As noted in the discussion of work redesign, most redesign efforts could be classified as either attempting to increase the motivational properties of work, or altering the technical or physical environment (typically to make work more efficient). Morgeson and Campion (2002) conducted a longitudinal quasi-experiment that sought to increase both satisfaction and efficiency in jobs at a pharmaceutical company. They found that when jobs were designed to increase only satisfaction or only efficiency, the common tradeoffs were present (e.g., increased or decreased satisfaction, training requirements). When jobs were designed to increase both satisfaction and efficiency, however, these tradeoffs were reduced.

Morgeson and Campion (2002) suggested that a work design process that explicitly considers both motivational and mechanistic aspects of work is key to avoiding the tradeoffs. Edwards et al. (2000) provide another possible explanation. They noted that the negative relationship typically found between motivational and mechanistic design is almost entirely due to a negative relationship between skill demands and task simplicity. Thus, as task simplicity increases, skill usage decreases, leading to the common tradeoffs between motivational and mechanistic design. But they also found that task simplicity and specialization, two key components of a mechanistic approach, were negatively related. This suggests that different aspects of mechanistic approaches are not necessarily consistent with one another. For example, task specialization may actually require high levels of certain skills. Thus, it may be possible to avoid the common tradeoffs by increasing task specialization because it makes work more efficient while at the same time increasing skill utilization (which makes work more motivating).

Campion et al. (2005) offer several different approaches that could be used when considering the potential tradeoffs of different work designs. The *compromise approach* involves “a direct judgment about the outcomes that are chosen as the focus of the work-redesign intervention” (p. 371). In this type of approach the desired outcomes drive the type of work design that is selected. The *level-separation approach* involves “designing different levels of the organization using different models” (p. 371). Unlike the compromise approach, the level-separation approach suggests looking at the organizational structure and hierarchy as a way to determine the appropriate work design. The *sequential approach* requires first implementing one model before implementing another, different model. Campion et al. (2005) offer several examples of how this could occur. For example, an organization may choose to use the mechanistic model to make jobs more

efficient, followed by applying the motivational model to make jobs more satisfying. The *synthesis approach* focuses on “specifying areas in which gains can be made based on one model without sacrificing the other models” (p. 371). The emphasis is placed on carefully examining the benefits of a model that can be gained without incurring its costs. Other approaches include the *team approach* (i.e., the use of team-based designs) and the *sociotechnical systems approach* (i.e., incorporating both changes to technological as well as human systems). Work design research would benefit from a closer examination of these types of approaches and the tradeoffs incurred in each.

CONCLUSION

As this review indicates, a large amount of research has been conducted under the auspices of work design. Although recently we have seen several extended work design frameworks, the majority of the research continues to use the model developed by Hackman and Oldham (1975, 1976). This has had a curiously narrowing effect that is best highlighted in Humphrey et al.’s (2007) meta-analysis. Although some topics have been investigated in great detail (e.g., the five-factor structure of the JDS), other topics have been all but neglected (e.g., nonmotivational explanations for the effect of work design). We have attempted to integrate past and current research on work design in an effort to highlight where we have been and where we stand as a field.

With this in mind, we highlight some potentially important work design areas that are in need of attention. First, as evidenced by recent meta-analytic findings, prior work design research has largely failed to acknowledge the work context. This is unfortunate given that the results show that contextual characteristics can impact important employee outcomes above and beyond the traditional motivating characteristics (Humphrey et al., 2007). Work design research would benefit from a better understanding of how employees react to different work characteristics in various contexts. For example, how do individuals respond to work design and redesign efforts in contexts with high levels of error criticality (i.e., consequences of failure)? Additional research is clearly needed in this area to help address these types of questions.

Work design research would also benefit from looking at the ways in which cultural differences impact employee perceptions and or reactions to changes in their work. Erez (2010) discusses both U.S. and Japanese approaches to work design and suggests that culture may act as a

moderator of the work design–outcome relationship. Research by Spector and colleagues (Spector et al., 2004, 2007) has empirically tested the moderating role of culture across multiple countries. For example, in a comparison of individualistic (U.S.) and collectivistic (Asia, East Europe, and Latin America) countries, they found that this cross-national difference moderated the relationship between work demands and both job satisfaction and turnover intentions. Such findings are promising and we look forward to additional research in this area. As discussed earlier, researchers have begun to translate the WDQ (Morgeson & Humphrey, 2006) into other languages. Hopefully this will help further work that intends to look at the impact of an extended set of work characteristics across different cultures and countries. By acknowledging the role of culture, we also acknowledge that work is embedded within a larger environment that extends beyond the organization.

A wider range of moderators of the work design–outcome relationship should be investigated. Research into Growth Need Strength has not yielded much support. Other important individual differences could include ability and personality. Surprisingly little work has been done that focuses on the moderating role of personality. In addition to the commonly studied Big Five personality traits, we have attempted to highlight some new individual differences that have yet to be largely explored within the work design domain. For example, how might one’s focus on the past, present, or future impact the ways in which one reacts to and experiences current job design features? Are individuals high in psychological flexibility better suited for certain types of jobs than others? Additional research may help shed light on these areas.

Finally, we are interested in exploring the idea of what makes “good” work. Barling et al. (2003) describe “high-quality work” as consisting of extensive training, variety, and autonomy; however, this label was prescribed by the authors. We believe that workers have different values, needs, and aspirations. As a result of these fundamental differences, they are likely to see their work in different ways and as such will have different definitions of what makes a “good” job. For example, a recent college graduate entering her first full-time job and a single mother who tries to balance both home and work will likely have very different definitions of what a good job entails. However, it may also be the case that there are some features of the job that are universally viewed as “good.” These perceptions around “good” work are likely to impact a wide range of employee attitudinal, behavioral, cognitive, and well-being outcomes.

INTRODUCTION

Stress in organizations is a widespread phenomenon with far-reaching practical and economic consequences. A recent study conducted on behalf of the American Psychological Association showed that between 2007 and 2010 about 70% of surveyed Americans perceived “work” to be one the major causes of stress (American Psychological Association, 2010). In 2009, about 40 percent of American adults reported that they feel tense and stressed out during a typical workday (American Psychological Association, 2009). A survey conducted in the European Union in 2005 found that on average 22% of workers experienced stress at work, with substantially higher levels in some of the countries (European Agency for Safety and Health at Work, 2009).

Experiencing organizational stress is related to health problems and their associated costs. A study based on more than 46,000 U.S. employees showed that health care costs were 46% higher for workers who experienced high levels of stress (Goetzel et al., 1998). Moreover, organizational stress is assumed to be related to increased absenteeism (Moreau et al., 2004), which is associated with high costs for organizations and society (Chandola, 2010; Cox, Griffiths, & Rial-González, 2000). It is estimated that the costs associated with work stress and other poor working conditions range between 0.5% and 3% of the gross

domestic product (GDP) in European countries such as the United Kingdom and the Netherlands (Chandola, 2010). In the long run, stress might lead to disabilities and mortality. For instance, a prospective study covering 25 years showed that employees who were exposed to high levels of job stressors, particularly in combination with low levels of job control, had a 2.2 times increased risk of cardiovascular mortality (Kivimäki et al., 2002).

Because stress in organizations is a highly relevant topic for individuals and organizations alike, there is enormous ongoing research activity in this area. Findings from past research have been summarized in previous review chapters and journal articles (Beehr & Newman, 1978; Danna & Griffin, 1999; Ganster & Schaubroeck, 1991; Kahn & Byosiére, 1992; McGrath, 1976; Sonnentag & Frese, 2003). In the past, researchers criticized studies on organizational stress for methodological weaknesses (Frese & Zapf, 1988; Kasl, 1978). Their main concerns referred to the cross-sectional design of many studies, common method variance and content overlap in predictor and outcome variables, and a focus on bivariate, linear relationships, neglecting possible moderator and nonlinear effects.

Over the years researchers witnessed methodological improvements in organizational stress studies (Beehr, 1998; Kahn & Byosiére, 1992). These improvements include (a) a better operationalization of basic concepts, which allows a better test of theoretical models (e.g. Edwards & Harrison, 1993; Wall, Jackson, Mullarkey, & Parker, 1996); (b) an increasing number of studies that use “objective” measures of stressors (Greiner, Ragland, Krause, Syme, & Fisher, 1997; Melamed, Ben-Avi,

Acknowledgment: We are grateful to Paul Spector and Doris Fay for their helpful comments and suggestions on an earlier version of this chapter, and to Anke Gries for her help when preparing this chapter.

Luz, & Green, 1995); (c) a steady increase in longitudinal studies (e.g., Bakker, Schaufeli, Sixma, Bosveld, & van Dierendonck, 2000; Dormann & Zapf, 1999; Xie, Schaubroeck, & Lam, 2008); (d) increased exploration of curvilinear effects (e.g., de Jonge & Schaufeli, 1998; Dollard, Winefield, Winefield, & de Jonge, 2000; Warr, 1990); and (e) the use of within-person (e.g., Kammeyer-Mueller, Judge, & Scott, 2009; Zohar, Tzischinski, & Epstein, 2003) and other multilevel designs (e.g., Jex & Bliese, 1999) and the implementation of growth curve models (e.g., Christie & Barling, 2009; Garst, Frese, & Molenaar, 2000).

This chapter builds on our earlier chapter (Sonnentag & Frese, 2003) and reviews research on stress in organizations. It aims at an extension of previous reviews by focusing more strongly on methodologically sound—although not perfect—studies. This approach gives us the opportunity to examine more deeply the processes and consequences associated with organizational stress. Specifically, we address the question whether methodologically improved studies contribute to a better understanding of organizational stress and its consequences for health and well-being. Our review also includes studies that look at outcomes such as job performance and other aspects of organizational behavior (e.g., organizational commitment and absenteeism).

In the first section of this chapter, we describe the stress concept and give an overview of stressors and stress reactions. The second section presents theories of organizational stress. The third section is devoted to empirical findings in organizational stress research. We describe the empirical evidence of main and moderator effects on the relationship between job stressors and individual health and well-being. We summarize research findings on the relationship between stress, performance, and other aspects of organizational behavior. In the fourth section we describe stress management interventions. In conclusion, we suggest a few research questions to be addressed in the future.

THE STRESS CONCEPT

Overview of Conceptualizations of Stress

On the most general level, one can differentiate between four stress concepts: (a) the stimulus concept, (b) the response concept, (c) the transactional concept, and (d) the discrepancy concept. The stimulus concept focuses on situational conditions or events. Within this conceptualization, certain stimuli are considered stressful, for example,

high time pressure, interpersonal conflict at work, or accidents. However, the stimulus concept is problematic because not all individuals react in a uniform manner to the same stressor. Nearly every situational condition or every event may evoke strain in some individuals. Although the stimulus conceptualization leads to conceptual problems, many researchers agree that there are subsets of stimuli that evoke strain in most individuals (Brief & George, 1995; Kahn & Byosiere, 1992).

The reaction concept focuses on physiological reactions as the crucial constituent of stress. According to the reaction concept, stress exists if an individual shows a specific reaction pattern, irrespective of situational characteristics (Selye, 1956). However, this conceptualization also has its shortcomings. It does not take into account that very different situations can result in the same physiological responses and that an individual's coping efforts may have an effect on his or her reactions, thus altering the stress response.

Another class of concepts refers to the interplay between person and situation. The transactional concept brought forward by Lazarus (1966) assumes that stress results from a transaction between the individual and the environment, including the individual's perceptions, expectations, interpretations, and coping responses. In terms of operationalizing and measuring stress in empirical studies this concept has not yet fully developed its potential. Often, proponents of the transactional concept actually rely in their research practice exclusively on verbal responses or physiological measures of strain as indicators of stress. By doing so, they implicitly apply the reaction concept. The discrepancy concept describes stress as an incongruence between what an individual desires and what the environment provides (Edwards, 1992). However, in operationalizing such a discrepancy, researchers face great difficulties.

Thus, *stress* is a broad term that conveys a variety of meanings. To avoid ambiguity, we refer to *stressors* and *stress reactions* throughout this chapter. For stress reactions, we use the term *strains* synonymously.

Stressors

Stressors are conditions and events that evoke strain (Kahn & Byosiere, 1992). Stressors can be single events (e.g., critical life events or traumatic experiences) and chronic problems that continue over a longer period of time. The latter often are micro-stressors, so-called *daily hassles* (Kanner, Coyne, Schaefer, & Lazarus, 1981), which include, for example, daily difficulties with finishing one's

TABLE 21.1 Overview of Stressors in Organizational Life

work on time or daily problems in dealing with difficult clients. Stressors can be grouped into the categories physical stressors, task-related job stressors, role stressors, social stressors, stressors related to the work schedule, career-related stressors, traumatic events, and stressful change processes (Table 21.1).

Physical stressors refer to aversive physical working conditions, including noise, dirt, heat, vibrations, and chemical or toxic substances. They also include poor ergonomic conditions at the workplace and safety hazards. *Task-related job stressors* appear while doing a task and they include high time pressure and work overload, high complexity at work, monotonous work, interruptions (e.g., caused by an unexpected computer shutdown), and situational constraints that potentially compromise task performance. Traditionally, *role stressors* comprise role overload, role conflict, and role ambiguity (Katz & Kahn, 1978). Role overload occurs when individuals have to do too much or too complicated work, role conflict refers to situations with conflicting role expectations, and role ambiguity refers to situations with unclear role expectations. More recently, facing illegitimate tasks has been described as a new aspect of a role-related stressor (Semmer, Tschan, Meier, Facchin, & Jacobshagen, 2010). *Social stressors* refer to poor social interactions with direct supervisors, coworkers, and others. These stressors include interpersonal conflicts at work, (sexual) harassment, mobbing or bullying, and other kinds of workplace aggression. Additionally, having to deal with highly difficult customers can also be conceptualized as social stressor. *Work schedule-related stressors* stem from working time arrangements. The most prominent and well-researched stressors in this category are night- and shiftwork. Additionally, long working hours and overtime belong to this category (Sparks, Cooper, Fried, & Shirom, 1997). *Career-related stressors* include job insecurity, underemployment, and poor career opportunities. *Traumatic stressors* are single events such as exposure to disasters, major accidents, or extremely dangerous activities. Soldiers, police personnel, and firefighters are particularly prone to exposure to such traumatic stressors

(Corneil, Beaton, Murphy, Johnson, & Pike, 1999). *Organizational change* can also be regarded as a stressor. Examples include mergers, downsizing, or the implementation of new technologies. These changes are stressful because they may result in other stressors such as job insecurity, overtime, and social conflicts.

These categories make sense intuitively, but largely lack an explicit theoretical foundation. There are only a few theoretically derived taxonomies of stressors. These taxonomies cover parts of potential stressors. Probably the most prominent taxonomy is the delineation of role stressors from role theory (Katz & Kahn, 1978), comprising role overload, role conflict, and role ambiguity. Meta-analyses reported relationships between role stressors on the one hand and impaired well-being and poor job performance on the other (Eatough, Chang, Miloslavic, & Johnson, 2011; Gilboa, Shirom, Fried, & Cooper, 2008; Jackson & Schuler; 1985).

Semmer (1984) and Leitner, Volpert, Greiner, Weber, and Hennes (1987) proposed a taxonomy of stressors based on action theory (cf. Frese & Zapf, 1994; Hacker, 1998). This taxonomy clusters stressors on the basis of how they disturb the regulation of goal-oriented action. Specifically, this taxonomy differentiates between regulation obstacles, regulation uncertainty, and overtaxing regulations. Regulation obstacles such as interruptions or organizational constraints make action regulation more difficult—if not impossible. Regulation uncertainty refers to uncertainties about how to reach the goal and include stressors such as lack of appropriate feedback, role conflicts, and role ambiguity. In the case of overtaxing regulation, regulation speed and intensity are the major problems. Typical examples are time pressure and concentration demands. This taxonomy has been successfully used in some studies (e.g., Frese, 1985; Greiner et al., 1997; Leitner & Resch, 2005).

Based on Lazarus and Folkman's (1984) differentiation between threat and challenge appraisals, researchers suggested that job stressors can be categorized either as challenge or hindrance stressors (Cavanaugh, Boswell, Roehling, & Boudreau, 2000; LePine, Podsakoff, & LePine, 2005). Typical examples of challenge stressors are high job demands, time pressure, and high levels of responsibility; typical examples of hindrance stressors comprise situational constraints, hassles, social conflicts, role ambiguity, and role conflict. Within this challenge-hindrance stressors framework, it is assumed that both challenge and hindrance stressors have negative effects for health and well-being, but that they differ with respect to their effects on performance. Specifically, it is assumed

that hindrance stressors impair performance, whereas challenge stressors should increase performance.

There is a long and ongoing debate on “objective” versus “subjective” approaches to the study of organizational stress (Frese & Zapf, 1988; Frese & Zapf, 1999; Kasl, 1998; Perrewé & Zellars, 1999; Schaubroeck, 1999). Often, subjective approaches have been linked to the use of self-report measures, while measures not using self-report were labeled *objective*. However, the distinction between objective and subjective approaches is not such a simple one. Frese and Zapf (1988) suggested another distinction: Objective approaches focus on events, processes, and workplace characteristics that are not related to the job holder’s perceptions and that exist irrespective of this individual’s cognitive and emotional reactions. Subjective approaches in contrast refer to events, processes, and workplace characteristics as perceived and appraised by the job holder. This debate is particularly important with respect to practical implications: It only makes sense to redesign jobs when strains can be attributed to objective stressors—and not primarily to appraisal processes.

Stress Reactions

Stress in organizations affects both the individual and the organization. Individuals can be affected at the physical, affective, and behavioral level, with such effects becoming evident not only at work, but also during leisure time. Stressors affect individuals and organizations within different time frames: stress reactions can occur immediately (short-term reactions) or may take a longer time to develop (long-term reactions). Table 21.2 gives an overview of stress reactions.

With respect to individual physiological responses, stress has an effect on the *cardiovascular system*. For example, individuals in so-called high-strain jobs (i.e., jobs with high demands and low job control; see Karasek, 1979) show higher blood pressure than individuals in other types of jobs (Schwartz, Pickering, & Landsbergis, 1996). Cardiovascular indicators such as blood pressure increase also temporarily during stressful workdays (Ilie, Dimotakis, & De Pater, 2010; see also Frankenhaeuser & Johansson, 1976). Interestingly, chronic job stressors may also influence cardiovascular responses to acute stressors (Chida & Hamer, 2008). Moreover, experiencing a stressful work situation is associated with increased levels of cholesterol and other metabolic and hemostatic risk factors for cardiovascular disease (Vrijkotte, van Doornen, & de Geus, 1999).

The cardiovascular system is partly affected by *hormones*. Stress affects the excretion of hormones such as

TABLE 21.2 Overview of Stress Reactions

	Short-Term Reactions	Long-Term Reactions

Behavioral	Cognitive reactions Increased effort Performance decrease Accidents	
Experienced by larger organizational units		
	Interpersonal conflicts	Increased turnover Absence rates
Experienced outside work		
	Slow unwinding Spillover of disturbed mood to private life	Poor well-being in other life domains Physical illness

catecholamines and corticosteroids (e.g., cortisol). With respect to catecholamines, it is well documented that the excretion of epinephrine (adrenaline) and norepinephrine (noradrenaline) increases as stress increases (Aronsson & Rissler, 1998; Frankenhaeuser, 1979; Frankenhaeuser & Johansson, 1976). The excretion of catecholamines seems to increase most when stressful working conditions are combined with inflexible working arrangements (Johansson, Aronsson, & Lindström, 1978; Melin, Lundberg, Soederlund, & Granqvist, 1999). Also cortisol levels increase when stress increases. However, the cortisol-reaction pattern is rather complex and not all stressors seem to elicit a cortisol reaction to the same degree (Kudielka, Hellhammer, & Wüst, 2009). For example, it has been argued that stressful situations characterized by self-evaluative threat and low controllability are particularly prone to lead to an increase in cortisol levels (Dickerson & Kemeny, 2004). Moreover, cognitive appraisals and emotions seem to play an important role (Denson, Spanovic, & Miller, 2009). These physiological reactions help in mobilizing additional effort for completing work assignments and upholding performance (Lundberg & Frankenhaeuser, 1978). This effort-mobilizing mechanism is also reflected in the cortisol awakening response (i.e., increase in cortisol levels after awaking in the morning), which is more pronounced in persons facing job stress (Chida & Steptoe, 2009). However, when experienced repeatedly and over a longer period of time, these physiological reactions may contribute to the development of illnesses, including coronary heart diseases.

Stress also has an effect on *immune functioning* (Denson et al., 2009; Herbert & Sheldon, 1993). Experiencing high levels of stress is detrimental for an individual's immune system. Although the exact underlying processes are still unclear, stress is associated with an increased risk of physical illnesses in the long run. Individuals experiencing high work stress are more likely to develop cardiovascular problems (Schnall, Landsbergis, & Baker, 1994) or musculoskeletal diseases (Bongers, de Winter, Kompier, & Hildebrandt, 1993). Other, longer term effects of job stressors include a broad range of other physiological symptoms, including headache, eye strain, and gastrointestinal problems (Nixon, Mazzola, Bauer, Krueger, & Spector, 2011).

The experience of stress is associated with *affective reactions*. In the short term, mood disturbances, particularly an increase in negative affective states, can occur (Rodell & Judge, 2009; Zohar, 1999). Such affective reactions seem to result mainly from a high workload, specific aversive events, and stressful achievement settings (Ilies et al., 2007; Pekrun & Frese, 1992; Weiss & Cropanzano, 1996). In the long run, well-being and mental health can suffer. There is evidence from longitudinal studies that stressful work situations are associated with an increased level of depressive symptoms (Schonfeld, 1992), psychosomatic complaints (Frese, 1985; Parkes, Menham, & Rabenau, 1994), and other distress symptoms (Leitner & Resch, 2005). Burnout is another long-term stress reaction. It is characterized by emotional exhaustion, depersonalization (cynism), and reduced personal accomplishment (Maslach & Jackson, 1981). Traditionally, burnout has been studied in human services and educational occupations, but nowadays there is clear evidence that members of other occupational groups may also develop burnout symptoms when facing stressful work situations (Maslach, Schaufeli, & Leiter, 2001).

Stressors can also have negative effects on the *behavioral level*. For example, under stressful situations attention is narrowed and working memory capacity is reduced. Moreover, reduced performance accuracy can be observed (Nieuwenhuys & Oudejans, 2010; Searle, Bright, & Bochner, 1999). When confronted with a stressor, individuals often increase their effort (Hockey, 1997). As a consequence, overall performance does not necessarily suffer (Tafalla & Evans, 1997); performance impairment probably depends on the type of stressor (LePine et al., 2005). Moreover, it has been observed that organizational stressors are related to violence such as sabotage, interpersonal aggression, and hostility (P. Y. Chen & Spector, 1992) and to unsafe behaviors, accidents, and injuries (Nahrgang,

Morgeson, & Hofmann, 2011). Stressors encountered at work are also related to other aspects of organizational behavior. There is clear evidence that individuals who experience stressors (particularly role stressors and hindrance stressors) are less committed to the organization, and show higher turnover intentions and actual turnover (Fried, Shirom, Gilboa, & Cooper, 2008; Meyer, Stanley, Herscovitch, & Topolnytsky, 2002; Podsakoff, LePine, & LePine, 2007).

Stress experienced at work can also become obvious *outside the work setting*. Mood disturbances associated with stressful working situations also have an effect on one's private life. For instance, experience-sampling studies have shown that mood experienced at work tends to spill over into the family domain (Ilies et al., 2007; Song, Foo, & Uy, 2008; Williams & Alliger, 1994). Moreover, experiencing a stressful work situation has effects on unwinding processes. For example, Frankenhaeuser (1981) examined adrenaline excretion rates during periods of high workload and showed that adrenaline excretion rates remained elevated during leisure time in the evening. When people are confronted with a high workload and situational constraints at work, they find it difficult to detach mentally from work and to engage in effortful leisure activities such as sports and exercise (Sonnetag & Jelden, 2009; Sonnetag, Kuttler, & Fritz, 2010). Additionally, stress reactions might not be limited to the person who is exposed to the stressful situation. Stress experienced at work is also related to impaired marital relationships (Story & Repetti, 2006) and a poor quality of parent-child interactions (Repetti & Wood, 1997; Roeters, van der Lippe, & Kluwer, 2010).

THEORIES ON ORGANIZATIONAL STRESS

Stress theories can be differentiated in models that describe the stress process itself and models that explain stress reactions, that is, the relationship between stressors and strains. The first type of model describes what happens when an individual is exposed to a stressor, while the second type of model specifies configurations of stressors that are associated with strains. Typically, this second type of model neglects process aspects.

It is beyond the scope of this chapter to provide an exhaustive presentation of all theories and models. Instead, we shall concentrate on models that have been influential in past theorizing and empirical research and on those that offer promising prospects for future research and practice. Interested readers may refer to Cooper

(1998) and Kahn and Byosiere (1992) for descriptions of more models.

Theoretical Models Focusing on the Stress Process

Models that focus on the stress process aim at a detailed description of what happens during the stress process. Major models in the area are the transactional stress model (Lazarus, 1966; Lazarus & Folkman, 1984) and (other) cybernetic models (Edwards, 1992).

The Transactional Stress Model

One of the most prominent models that describes the stress process is the transactional model by Lazarus (1966; Lazarus & Folkman, 1984). Lazarus and Folkman define *psychological stress* as “a particular relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being” (p. 19). Thus, Lazarus and Folkman assume that cognitive appraisals play a crucial role in the stress process. Appraisal processes refer to an individual’s categorization and evaluation of an encounter with respect to this individual’s well-being. Specifically, primary and secondary appraisal can be differentiated. During primary appraisal, encounters are categorized as irrelevant, benign-positive, or stressful. Stress appraisals comprise harm/loss, threat, and challenge. During secondary appraisals, individuals evaluate what can be done in the face of the stressful encounter; that is, they tax their coping options. On the basis of primary and secondary appraisals, individuals start their coping processes, which can stimulate reappraisal processes.

To arrive at a better understanding of the stress process and how it develops over time, Lazarus (1991) suggested putting more emphasis on an intraindividual analysis of the stress phenomenon, for example by studying the same persons in different contexts over time. Folkman, Lazarus, Dunkel-Schetter, DeLongis, and Gruen (1986) described an early study that applied such an approach. During recent years, more and more studies took an intraindividual perspective on job stress (Daniels & Harris, 2005; Gross et al., 2011).

Cybernetic Model

Edwards (1992) proposed a cybernetic model of organizational stress (for a related model, see Cummings & Cooper, 1979, 1998). Edwards summarized earlier approaches on stress, which implicitly assumed cybernetic principles (e.g., Kahn, Wolfe, Quinn, Snoek, & Rosenthal, 1964; McGrath, 1976) and explicitly built on Carver and

Scheier’s (1982) work on cybernetics as a general theory of human behavior.

Edwards (1992) defines *stress* as “a discrepancy between an employee’s perceived state and desired state, provided that the presence of this discrepancy is considered important by the employee” (p. 245). Thus, stress occurs when the comparison between an individual’s perception and his or her desire results in a discrepancy. The perception is assumed to be influenced by the physical and social environment, personal characteristics of the individual, the individual’s cognitive construction of reality, and social information. Stress, as the discrepancy between perception and desires, affects two outcomes: the individual’s well-being and his or her coping efforts. Additionally, reciprocal effects between well-being and coping are assumed. Moreover, coping may have an effect on the individual and the situation, the individual’s desires, and the duration of the stressful situation and the importance attached to it. The effects of the discrepancy on well-being and coping efforts are moderated by additional factors such as the importance of the discrepancy and its duration.

There is empirical research on isolated aspects of the cybernetic model (e.g., on the effects of discrepancies between perceptions and desires on well-being) (see Edwards, 1991). Moreover, a coping scale has been developed that refers to basic cybernetic ideas (Edwards & Baglioni, 1993; Guppy et al., 2004). However, it is particularly difficult to examine the core assumptions of the cybernetic model in one single study. Such a study must include separate measures of perceptions, desires, importance, duration, well-being, and coping. The greatest challenge will be to design nonconfounded measures of individual perception, objective characteristics of the environment, of the individual’s cognitive construction of reality, and of social information processes.

Theoretical Models on the Relationship Between Stressful Situations and Strains

These models specify the configuration of workplace factors that are associated with strains (i.e., stress reactions). Major models include the person–environment fit theory (Harrison, 1978), the job demand–job control model (Karasek, 1979) and its more recent refinements (Demerouti, Bakker, Nachreiner, & Schaufeli, 2001; de Jonge & Dormann, 2006), the vitamin model (Warr, 1987), and the effort–reward imbalance model (Siegrist, 1996).

Person–Environment Fit Theory

Person–environment (P-E) fit theory assumes that stress occurs because of a misfit between the individual and

the environment (for an overview, see Edwards, 1998; Harrison, 1978). Thus, it is neither the person nor the situation alone that causes stress experiences and strains. The theory describes two types of misfit between an individual and the environment. The first type refers to the fit between the demands of the environment and the abilities and competencies of the persons (demands–abilities fit). The second type refers to the fit between the needs of the person and supplies from the environment (needs–supplies fit).

At the conceptual level, P-E fit theory differentiates between the objective and the subjective person as well as between the objective and the subjective environment (Harrison, 1978). Objective person and objective environment refer to the individual needs, abilities and competencies and to environmental supplies and demands as they actually exist (i.e., independently of the person's perceptions). Subjective person and subjective environment refer to the individual's perceptions. Therefore, fit can refer to the congruence between (a) objective environment and objective person, (b) subjective environment and subjective person, (c) subjective and objective environment (i.e., contact with reality), and (d) subjective and objective person (i.e., accuracy of self-assessment).

P-E fit theory argues that the objective person and environment affect the subjective person and environment and that a misfit between the subjective environment and the subjective person produces strain. Strain increases as demands exceed abilities and as needs exceed supplies. When abilities exceed demands, strain may increase, decrease, or remain stable. Similarly, when supplies exceed needs, strain may increase, decrease, or remain stable. The exact picture of the relationships depends on the content and importance of the dimension in question.

In a classic study, French, Caplan, and Harrison (1982) explicitly tested assumptions derived from P-E fit theory. P-E misfit was associated with psychological, physical, and biological strains. Subsequent studies resulted in similar findings and identified a needs–supplies misfit as the strongest predictor of strain (Edwards, 1991). However, many of these studies have been criticized for methodological shortcomings, particularly the operationalization of P-E fit as a difference score (Edwards, 1995). Subsequent studies overcame these problems by examining three-dimensional relationships of the person and environment with strain measures. These studies partially confirmed the basic assumption of P-E-fit theory that strain increases when fit between the person and his or her work environment decreases (Edwards, 1996; Edwards & Harrison, 1993). Meta-analytical evidence also suggests that

demands–abilities fit and needs–supply fit are negatively related to strain symptoms (Kristof-Brown, Zimmerman, & Johnson, 2005).

Job Demand–Job Control Model

The job demand–job control model differentiates between two basic dimensions of workplace factors, namely, job demands and job decision latitude (Karasek, 1979). Job demands are the work load demands put on the employee. Job decision latitude refers to the employee's decision authority and his or her skill discretion. Karasek combined the two dimensions of job demands and job decision latitude in a 2×2 matrix of jobs: jobs low on demands and low on decision latitude (“passive” jobs), jobs low on demands and high on decision latitude (“low-strain” jobs), jobs high on demands and low on decision latitude (“high-strain” jobs), and jobs high on demands and high on decision latitude (“active” jobs).

With respect to stress reactions, Karasek (1979) proposed that the combination of high demands and low decision latitude in high-strain jobs is most detrimental for people's health and well-being. The combination of high demands and high decision latitude in active jobs, however, is assumed to produce little harm for the individual. Stated differently, the model basically assumes that high decision latitude attenuates the negative effects of high demands. During the past decades, the job demand–job control model stimulated a large amount of empirical research. There is some, although not unequivocal, support for the model. We will discuss findings from this research in more detail later in this chapter when presenting studies on job control.

Based on the job demands–job control model, Demerouti et al. (2001) proposed a more general job demands–job resources model. According to this model, decision latitude (or job control) is not the only job resource that matters when it comes to job stress. Demerouti and her coworkers argued that other resources such as feedback, reward, participation, and supervisor support can buffer the negative effects of job demands on strain reactions and poor health. Empirical studies tend to support the basic assumptions of the model (for an overview, see also Bakker & Demerouti, 2007).

Another refinement of the job demand–job control model was suggested by de Jonge and Dormann (2006). Proposing a “triple-match principle” (p. 1359), these authors argued that resources are more likely to buffer the effects of stressors when they match the specific content of the stressors. For instance, cognitive resources should be most effective for buffering cognitive stressors, and

emotional resources should be most effective for buffering emotional stressors.

Vitamin Model

Warr (1987) proposed a vitamin model to specify the relationships between stressors and employee health and well-being. The vitamin model claims nonlinear relationships between work characteristics and individual outcomes. Drawing an analogy to the effects vitamins have on the human body, Warr assumes that there are two types of work characteristics. First, some work characteristics are assumed to have a constant effect on the individual; that is, positive outcomes increase as the work characteristic increases, but only up to a certain point; beyond that point, any increase of the level of this work characteristic does not have any further effect, similar to vitamin C. Examples are salary, safety, and task significance. Second, other work characteristics are assumed to have a curvilinear relationship with well-being variables. Similar to vitamin D, they are positive to a certain degree, but then every further increase has a negative effect. Examples of these work features are job autonomy, social support, and skill utilization. In terms of stress, this model implies that a specific amount of job autonomy, job demands, social support, skill utilization, skill variety, and task feedback is beneficial for the individual, but a very high level of these job characteristics creates a stressful situation. In contrast, high levels of salary, safety, and task significance do not show this detrimental effect. Empirical support for this model is mixed (de Jonge & Schaufeli, 1998; Parkes, 1991; Warr, 1990).

Effort–Reward Imbalance Model

A variant of the P-E fit model is Siegrist's (1996) effort–reward imbalance model. Basically, the effort–reward imbalance model assumes that a lack of reciprocity between costs and rewards is experienced as stressful and results in strains. More specifically, the degree to which an individual's efforts at work are rewarded or not is crucial for this person's health and well-being. Effort may be the response to both extrinsic (e.g., obligations and demands inherent in the situation) and to intrinsic demands (e.g., resulting from a high need for control or approval). Rewards comprise money, esteem, and status control, such as job stability, status consistency, and career advancement. In essence, the model assumes that situations in which high efforts do not correspond to high rewards result in distress situations and high arousal.

Empirical studies showed that a combination of high effort and low reward predicted an increased risk of poor health (for an overview, see Van Veghel, De Jonge,

Bosma, & Schaufeli, 2005). For instance, a longitudinal study with blue-collar workers demonstrated that experiencing an effort–reward imbalance was associated with a 6.15 times higher risk of developing coronary heart disease 6.5 years later (Siegrist, Peter, Junge, Cremer, & Seidel, 1990; see also Bosma, Peter, Siegrist, & Marmot, 1998).

EMPIRICAL EVIDENCE

Main Effects of Stressful Situations on Individual Well-Being and Health

There is consistent evidence that perceived job stressors are associated with poor well-being and poor health (for meta-analyses, see Crawford, LePine, & Rich, 2010; Jackson & Schuler, 1985; Lee & Ashforth, 1996). However, most of these studies are cross-sectional in nature and based on same-source self-report measures. Many researchers criticized these predominant features of organizational stress studies (Frese & Zapf, 1988; Kasl, 1978; Zapf, Dormann, & Frese, 1996). Cross-sectional designs allow no inference about causality, empirical relationships between stressors and strains might be caused by third variables (e.g., socioeconomic background or negative affectivity), and strains may affect stressors, as spelled out in the drift hypothesis. The drift hypothesis implies that individuals with poor health are unable to retain favorable working conditions in the long run, while healthier individuals are promoted into better, that is, less stressful jobs (Frese, 1985). Health and well-being might also affect the perception of stressors, as individuals with poor health overestimate the stressfulness of their jobs (De Lange, Taris, Kompier, Houtmon, & Bongers, 2005). Additionally, same-source measures often used in organizational stress research suffer from common method variance and therefore may result in an overestimation of true relationships (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003).

Evidence from Studies with Objective Measures of Stressors

To examine whether the relationship between stressors and strains can be primarily attributed to the use of self-report measures and the associated methodological problems, studies are needed in which stressors are assessed by non-self-report measures. There is a growing number of such studies. In some of these studies, researchers inferred objective stressors from occupational titles and similar information. Analyses revealed significant relationships between stressful jobs and poor health and well-being

(e.g., Tsutsumi, Theorell, Hallqvist, Reuterwall, & de Faire, 1999).

In other studies, researchers assessed objective stressors by observational methods. These studies also revealed associations between stressors and impaired health and well-being (Griffin, Greiner, Stansfeld, & Marmot, 2007; Rau, 2004). For example, Frese (1985) found correlations of $r = 0.18$ and $r = 0.19$ between observer ratings of psychological stressors and psychosomatic complaints. Melamed et al. (1995) assessed monotony with observational ratings and found that short-cycle and medium-cycle repetitive work was significantly associated with psychological distress, particularly in women. Greiner et al. (1997) reported increased odd ratios of psychosomatic complaints in observed high-stress jobs.

In summary, these findings show that job stressors are related to poor health and well-being—even when objective stressor measures are used. Often, the correlations between objective stressor measures and strains are smaller in size than the correlations between self-report measures of stressors and strains (see Frese, 1985), but they do not break down completely. This pattern of findings suggests that common method variance inflates the relationships between self-reported stressors and self-reported strains, but does not fully explain the empirical relationship between stressors and strains. For methodological reasons, the correlations found between objective stressors and self-reported strains present the lower boundary of the stressor–ill health relationships (Frese, 1993).

Evidence from Longitudinal Studies

To explore the causal processes between stressors and strains in more detail, longitudinal research is needed. Although they do not allow for causal conclusions in a strict sense, longitudinal studies at least allow researchers to rule out some of the alternative interpretations. During the past decades, a large number of longitudinal studies on the relationship between job stressors on the one hand and health and well-being outcomes on the other have been published, making a detailed report of each individual study not feasible. Therefore, in this section we give a quantitative overview of the study findings. When selecting studies for this overview we focused on studies that examined lagged effects (i.e., studies that predicted strains at Time 2 from stressors assessed at Time 1); we excluded studies that looked at concurrent effects (i.e., studies with stressors and strains assessed at the same point in time).

Based on earlier review chapters and articles (De Lange, Taris, Kompier, Houtmon, & Bongers, 2003; Sonnentag & Frese 2003), and a manual search in relevant journals,

we located 66 papers that reported usable data, comprising a total of 70 studies with a total of 187 effect sizes.¹ The average sample size of these studies was 722 ($SD = 1,274$), ranging from 52 to 6,286. The average time lag between two measurement points was 25.7 months ($SD = 31.6$), ranging from 1 to 144 months. Of the 70 studies, 31 studies (44.3%) used an ordinary least squares regression approach for analyzing the data, 28 studies (40.0%) used structural equation modeling, 7 studies (10%) used logistic regression, and the remaining 4 studies (5.7%) used other approaches (e.g., cross-lagged panel correlations). Interestingly, 66 of the studies (94.3%) controlled for the stability of the outcome measure (i.e., took the initial level of the strain measure into account).

Similar to the approach of Porras and Robertson (1992), for each study we coded if the empirical relationship between a specific job stressor (e.g., workload) and a specific strain outcome (e.g., psychosomatic complaints) was significant. When studies included multiple stressors and/or multiple strain outcomes, we coded the relationship between each stressor and each strain outcome separately.

The left-hand column of Figure 21.1 shows the overall findings. In the 70 studies examined, 23 (32.9%) reported a significant positive relationship between job stressors and strain outcomes and 18 (25.7%) reported significant positive relationships for some of the job stressors and/or strain outcomes, but not all. Twenty-eight studies (40.0%) reported no significant relationship between job stressors and strain outcomes, and one study (1.4%) reported a negative relationship between job stressors and strain outcomes. Of the 70 studies, 26 tested reverse causation, that is, examined whether strains predict job stressors over time. The right-hand column of Figure 21.1 shows that in the majority of these 26 studies (73.1%), no evidence for reverse causation was found. In 4 studies (15.4%) a reverse effect was reported for all the job stressors and strains examined, and in 3 studies (11.5%) reverse causation was reported for some of the job stressors and/or strains.

Figure 21.2 shows the breakdown of the findings by time lag. Of the 17 studies that used time lags of less than 1 year, 47.1% revealed positive relationships between job stressors and strains, 17.6% revealed positive relationships for some of the job stressors and/or strains, and 35.3% showed no significant relationships. With time lags of 1 year and longer, the percentage of significant positive relationships tends to decrease, and with time lags longer

¹A list of all studies included in this analysis can be obtained from the first author upon request.

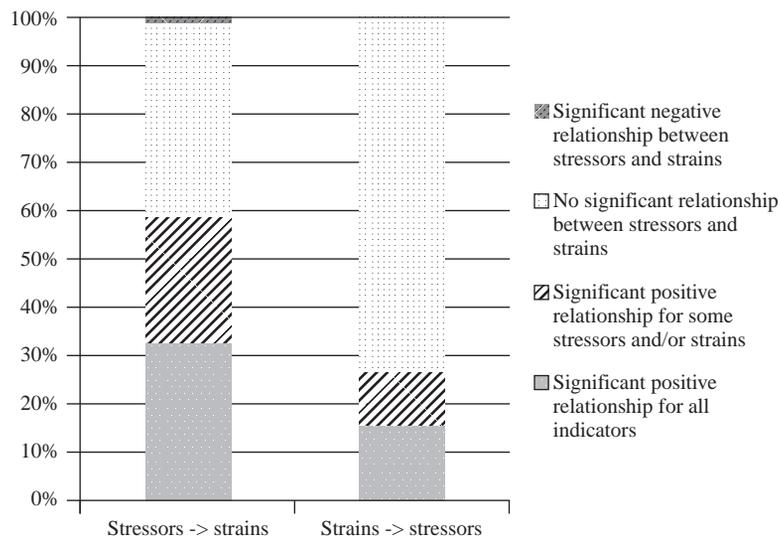

Figure 21.1 Overall findings from longitudinal studies testing lagged relationships from job stressors on strains and from strains on job stressors

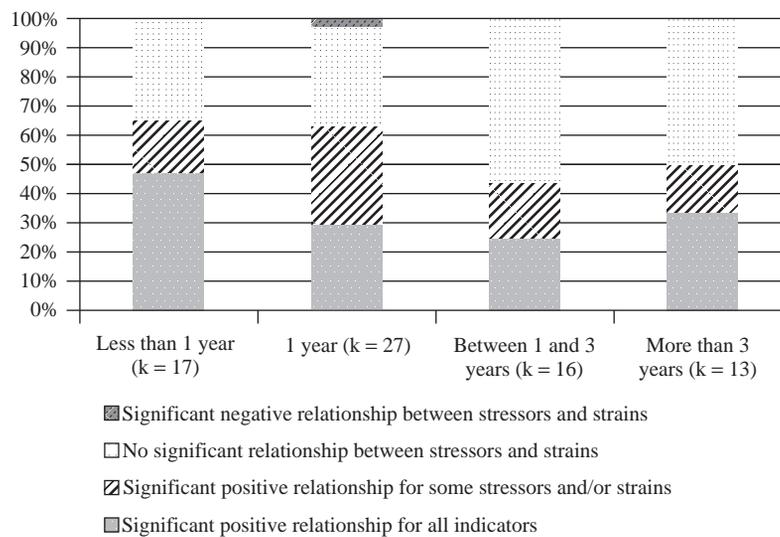

Figure 21.2 Breakdown of longitudinal findings by time lag

than 1 year, the percentage of nonsignificant relationship increases. This pattern of findings suggests that it is more likely to find a significant relationship within time lags of 1 year and shorter, most probably because job stressors unfold their negative effects within a relatively short period of time.

Figure 21.3 shows the breakdown for sample size. As a general pattern it becomes obvious that with an increase in sample size until $N = 1,000$, the percentage of significant positive relationships between job stressors and strains decreases. However, studies with large sample sizes ($N > 1,000$) very often show significant relationships between

job stressors and strains, at least for some of the included job stressors and/or strains. This finding can be attributed to the fact that larger sample sizes are associated with a better statistical power. The finding that there are less (partly) significant findings for sample sizes between 100 and 1,000 than for smaller sample sizes is surprising. A possible explanation is that studies with sample sizes exceeding 100 might have reported interaction effects. Thus, these studies might have been submitted for publication also in the absence of a main effect of job stressors, whereas significant interaction effects were rather unlikely in studies with smaller sample sizes.

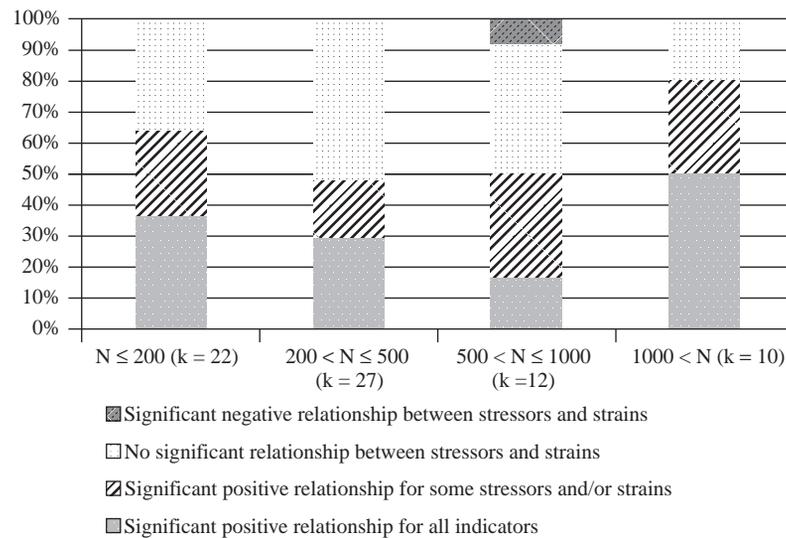

Figure 21.3 Breakdown of longitudinal findings by sample size

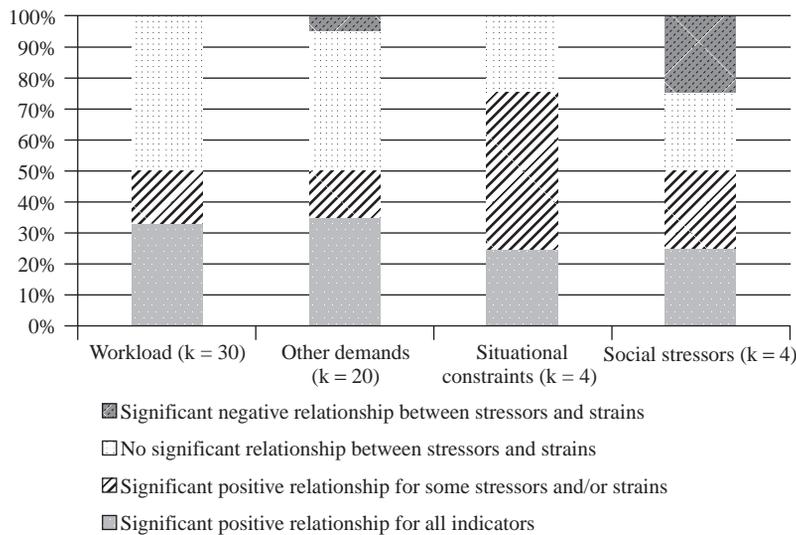

Figure 21.4 Breakdown of longitudinal findings by stressor type

Figure 21.4 displays the breakdown by stressor type. The findings for workload and other demands (e.g., emotional or physical demands) largely mirror the overall pattern of findings as displayed in Figure 21.1. This result is not surprising because workload and other demands are the most frequently studied job stressors. Significant findings were less frequently observed with respect to situational constraints and social stressors—however, conclusions might be premature because the number of longitudinal studies that focused on these stressors is rather small.

Figure 21.5 shows the findings for various strain outcomes. Significant (or partly significant) relationships

became particularly obvious when severe illnesses were used as strain measures. Significant (or partly significant) relationships were observed less frequently with respect to emotional exhaustion.

Taken together, more than 50% of all studies reported significant relationships between job stressors and strains, for at least some of the stressors and/or strains. With respect to reverse causation, the percentage of (partly) significant findings was much smaller. Overall, this pattern of findings suggests that the causality from job stressors to strains is stronger than the reverse causation. Nevertheless, it has to be noted that about 40% of all studies found no significant association between job stressors and strains,

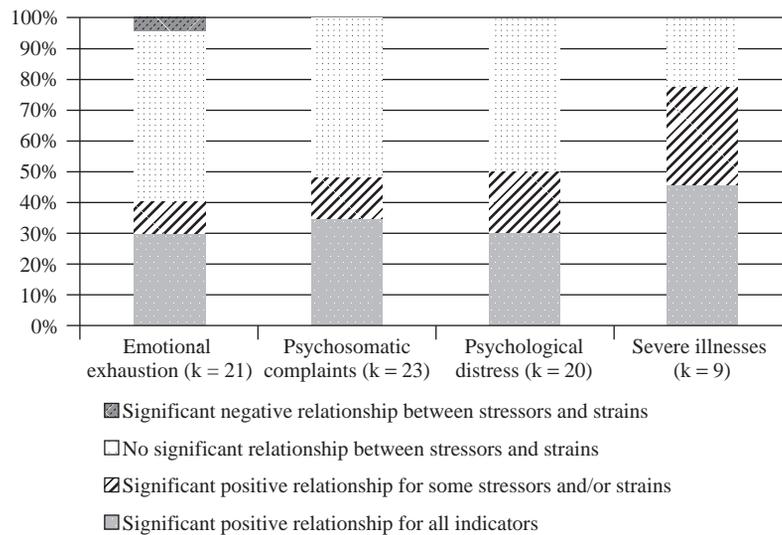

Figure 21.5 Breakdown of longitudinal findings by type of strain

suggesting that there is no deterministic relationship between job stressors and health or well-being outcomes. Of course, moderator variables might play an important role here. We will discuss moderator effects in the next section of this chapter. Moreover, it has to be noted that there might be differential reactions to job stressors: For some persons, high job demands might be associated with an increase of emotional exhaustion, whereas others might develop physical health problems as a reaction to high job demands.

The Role of Resources

Stressors do not necessarily have a negative effect on the individual. The degree to which a stressful work situation impacts the individual might be contingent on the availability of resources. Hobfoll (1998) defines resources as “objects, conditions, personal characteristics, and energies that are either themselves valued for survival, directly or indirectly, or that serve as a means of achieving these ends” (p. 54). With respect to organizational stress, resources refer to conditions within the work situation (job resources) and to individual characteristics that can be used to attain goals (personal resources). Both with respect to the advancement of stress theory and practical implications it is highly relevant to establish whether these resources buffer (i.e., moderate) the effects of stressors on strains. Job resources most often studied were job control and social support. Personal resources comprise—among others—coping styles, core self-evaluations, and resources gained from recovery processes.

Job Control

Job control refers to one’s opportunity to influence one’s activities in relation to a higher order goal (Frese, 1989). P. R. Jackson, Wall, Martin, and Davids (1993) differentiated between control over temporal features and control over work methods. Many studies addressed the question whether high job control at work buffers the negative effects of a stressful work situation on health and well-being. Most of these studies have been conducted within the framework of Karasek’s (1979) job demand–job control model.

Epidemiological studies on cardiovascular diseases as an outcome variable tended to confirm the major assumptions of Karasek’s model (for reviews, see Kristensen, 1995; Schnall et al., 1994; Theorell & Karasek, 1996). Individuals in high-strain jobs (i.e., jobs with high demands and low control) often suffered from cardiovascular illnesses. Moreover, in about half of the studies, high-strain jobs were associated with cardiovascular risk factors such as high blood pressure and smoking (Schnall et al., 1994).

With respect to other outcomes, including psychological well-being and mental health, the findings are less conclusive. Systematic qualitative reviews that summarized more than a total of 120 individual studies reported rather consistent evidence for the assumed main effects of the Karasek model (De Lange et al., 2003; Häusser, Mojzisch, Niesel, & Schulz-Hardt, 2010; Van der Doef & Maes, 1999): When job demands are high and when job control is low it is more likely that employees experience symptoms of poor mental health and impaired well-being.

Importantly, this pattern is also found in longitudinal studies (De Lange et al., 2003) and is largely confirmed with meta-analytic approaches (Crawford et al., 2010; Humphrey, Nahrgang, & Morgeson, 2007). However, evidence for the hypothesized moderator effect of job control is rather poor (Häusser et al., 2010; Van der Doef & Maes, 1999), also when excluding poorly designed studies (De Lange et al., 2003).

During the past decades, several explanations for this failure to find convincing support for the buffer hypothesis have been offered: First, it has been argued that additional variables might play a role. For instance, Johnson and Hall (1988) have proposed that social support might buffer the negative effects of the combination of high demands and low control. Overall, empirical support for this model has remained inconclusive (Häusser et al., 2010; Van der Doef & Maes, 1999). Second, Wall et al. (1996) have argued that Karasek's (1979) measure of decision latitude (used in many studies) is a conglomerate of various aspects of control such as decision over working methods, decision over scheduling of one's tasks, aspects of skill use, and task variety. Probably only proper job control attenuates the negative effects of high demands, while skill use and task variety do not. Some studies found support for Wall et al.'s assumption (De Croon, Van der Beek, Blonk, & Frings-Dresen, 2000; Sargent & Terry, 1998; Wall et al., 1996), but other studies that used similar operationalizations of job control failed to find the proposed interaction effect. Third, de Jonge and Dormann (2006) suggested that job resources are only beneficial if they match the specificities of the stressor that has to be buffered. Thus, job control should only show a moderator effect when it helps to influence the processes associated with the specific stressor. Although empirical findings drawing on this framework are encouraging, not all interaction terms with "matching" stressors and resources turn significant (Chrisopoulos, Dollard, Winefield, & Dormann, 2010; de Jonge & Dormann, 2006). Fourth, Warr (1987) and Frese (1989) have argued that at work it should be very difficult to find interaction effects of stressors and control: Control implies that people can do something about the stressors. If people are bothered by stressors, they reduce them; but they can only reduce stressors if they have control. If stressors continue to exist, this may be because they are uncontrollable by definition. Because uncontrollability and stressors are intertwined, it is difficult to find an interaction effect.

Interestingly, experimental research tends to support the job demand–job control model. In these experiments, interaction effects of perceived demands and perceived control on dependent measures such as anxiety, task

satisfaction, and subjective task performance were found (Hockey & Earle, 2006; Jimmieson & Terry, 1997; Perrewé & Ganster, 1989), although there is also disconfirming evidence (Perrewé & Ganster, 1989; Searle et al., 1999). A recent experiment suggests that an individual's desire for control might play an important role here: For individuals with a high desire for control, actual control buffered the negative impact of high demands, whereas for individuals with a low desire for control, actual control was irrelevant (Parker, Jimmieson, & Amiot, 2009). Therefore, field studies might want to pay more attention to individuals' desire for control and related constructs.

In summary, there is strong empirical evidence for the additive main effects of job demands and low job control. Individuals in high-strain jobs that combine high demands with low control show the lowest well-being scores and suffer most from illnesses. However, the interaction effect has received far less support. Adequate operationalization of job control and a match between control and demands may be crucial for finding significant interaction effects. Overall, Karasek's model (1979) has contributed to a fair amount of empirical controversy, which has been fruitful. Given the arguments above and the experimental findings, the fact that noncontrol and stressors produce at least additive effects and that a number of field studies find an interaction effect after all, we tend to think that it is legitimate to consider job control one of the prime resources.

Social Support and Work Group Factors

Social support is important for protecting an individual's health and well-being. It can be characterized as "resources provided by others" (Cohen & Syme, 1985) and comprises emotional, informational, and instrumental support (House, 1981). In general, the literature assumes that the beneficial effect of social support works via both main and interaction effects. A meta-analysis that addressed the main effect and summarized studies examining a broad range of strain symptoms has shown that social support is negatively associated with strains (Viswesvaran, Sanchez, & Fisher, 1999). A more recent meta-analysis that focused on burnout points in a similar direction with social support being negatively related to all three burnout indicators (emotional exhaustion, depersonalization, and reduced personal accomplishment). Work support showed stronger associations than nonwork support, particularly with respect to emotional exhaustion (Halbesleben, 2006; see also Nahrgang et al., 2011).

With respect to the interaction effect, cross-sectional studies suggest that social support has the potential to

buffer the negative effects of stressors (for a review, see Kahn & Byosiere, 1992). Importantly, it is most likely that social support functions as a buffer in the stressor–strain relationship when the support available matches “the specific need elicited by a stressful event” (Cohen & Wills, 1985; p. 314; see also Daniels & de Jonge, 2010), when employees identify with their social work context (Jim-mieson, McKimmie, Hannam, & Gallagher, 2010), and when the overall exchange pattern is perceived to be reciprocal, that is, when the amount of social support received equals the amount of social support provided to others (Nahum-Shani & Bamberger, 2011).

Dormann and Zapf (1999) reviewed 10 longitudinal studies published between 1985 and 1999 that examined the interaction effect of social support. Three of these studies found no moderator effects. In some of the other studies, moderator effects missed the conventional significance level or were significant only for a small portion of all the effects tested. Thus, the evidence for an across-the-board moderator effect of social support is not very strong. However, in correspondence to the stress-matching hypothesis (Cohen & Wills, 1985), Frese (1999) found the strongest effects for social stressors and socially related aspects of psychological dysfunctioning. Moreover, Nahum-Shani and Bamberger (2011) found a longitudinal buffer effect of social support only when the overall exchange pattern of social support was reciprocal. In addition, the beneficial moderator effect of social support might only unfold within specific time frames (Dormann & Zapf, 1999). More research is needed that specifies the conditions and temporal patterns when social support buffers the negative effects of job stressors. It is particularly important to take into consideration that social support sometimes might even have negative effects (Peeters, Buunk, & Schaufeli, 1995; Schaubroeck & Fink, 1998).

In addition to social support, group work factors such as group cohesion or team climate play a role when it comes to stress in organizations. First, research suggests that group cohesion, group autonomy, and favorable team climates are associated with team members’ well-being (Carter & West, 1998; Sonnentag, Brodbeck, Heinbokel, & Stolte, 1994; van Mierlo, Rutte, Vermunt, Kompier, & Doorewaard, 2007). Second, work group factors such as psychological safety (Edmondson, 1999) or collective efficacy (Schaubroeck, Lam, & Xie, 2000) might buffer the negative effects of stressors (see also Bliese & Britt, 2001). Third, there is increasing evidence that emotional contagion occurs in work groups (Bakker & Schaufeli, 2000; Totterdell, Kellett, Techmann, & Briner, 1998). Emotional contagion refers to processes by which an

individual’s mood is “transmitted” to other persons, for example, other team members. On the one hand, this phenomenon implies that a stressful event can impact more persons than those directly faced with the stressor (Westman, Roziner, Bakker, & Sonnentag, 2011). On the other, other team members’ positive mood can serve as a resource when some of the team members are confronted with a stressor.

Coping Styles

A favorable coping style can be a core resource for bolstering an individual’s health and well-being. Lazarus and Folkman (1984) defined *coping* as “constantly changing cognitive and behavioral efforts to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person” (p. 141). They differentiated between problem-focused and emotion-focused forms of coping. Problem-focused coping includes problem-solving behaviors that aim at directly changing the stressor, other aspects of the environment, or one’s own behavior. Emotion-focused coping refers to attempts to manage cognitions or emotions directly (for a critique and extension, see Semmer, 1996).

Problem-focused coping has been found to be positively related to mental health and well-being while emotion-focused coping and an additional style of avoidance coping were often found to be associated with poor well-being (Guppy & Weatherston, 1997; Hart, Wearing, & Headey, 1995; Leiter, 1991; Sears, Urizar, & Evans, 2000).

With respect to moderator effects, empirical findings are less conclusive. Many studies did not find the hypothesized moderator effects of coping (e.g., Ingledew, Hardy, & Cooper, 1997). Most studies that did find a moderator effect, identified problem-solving coping as a favourable coping style, while emotion-focused coping turned out as unfavourable (Parkes, 1990). This pattern of findings implies that individuals who approach the stressors directly or engage in other problem-solving behaviors are better off than individuals who concentrate on the management of their emotions and cognitions.

Studies, however, suggest that in many instances problem-focused coping alone might not be sufficient for buffering the negative effects of stressors. For instance, coping behavior should match the situation in order to be effective (Perrez & Reicherts, 1992). A study in a hospital setting supports this assumption (de Rijk, Le Blanc, Schaufeli, & de Jonge, 1998): Problem-focused coping was found to be superior only in situations in which nurses could exert control over their work situation.

In low-control situations, attempts of problem-focused coping were negatively associated with individuals' well-being. Moreover, sometimes a combination of problem-focused coping with other coping approaches seems to be most beneficial (Shimazu & Schaufeli, 2007).

Core Self-Evaluations

There is a long tradition in job-stress research to examine individual characteristics such as locus of control, self-esteem, self-efficacy, and emotional stability in their relation to individual health and well-being (for a review, see Kahn & Byosiere, 1992). More recently, Judge, Locke, Durham, and Kluger (1998) have subsumed these traits under the higher order construct of "core self-evaluations." Meta-analytic evidence suggests that these core self-evaluations, comprising an internal locus of control, high self-esteem, high self-efficacy, and emotional stability, are negatively related to a broad range of strain symptoms (Kammeyer-Mueller et al., 2009), including burnout (Alarcon, Eschleman, & Bowling, 2009).

With respect to potential moderator effects of core self-evaluations on the stressor-strain relationship, the findings are less supportive. Neither Best, Stapleton, and Downey (2005) nor Kammeyer-Mueller et al. (2009) found evidence for a moderator effect of core self-evaluations. However, it has to be noted that for some of the low-order constructs, moderator effects have been detected in empirical studies, for instance, for self-efficacy (Jex & Bliese, 1999; Van Yperen, 1998) or emotional stability (Kammeyer-Mueller et al., 2009). Moreover, there is evidence that the interaction patterns might be more complex: Three-way interactions have been reported for locus of control (Daniels & Guppy, 1994; Parkes, 1991) and self-efficacy (Schaubroeck et al., 2000; Schaubroeck & Merritt, 1997).

Recovery Processes

For maintaining health and well-being, it is important not only whether people are exposed to stressors and how they respond to these stressors, but also how they unwind and recuperate from the stress experience (Eden, 2001; McEwen, 1998; Meijman & Mulder, 1998). A number of studies have addressed the beneficial effects of such recovery processes. Cross-sectional and diary studies showed that when people engage in leisure activities (e.g., sports and exercise), and when they psychologically detach (i.e., mentally disengage) from work and relax during their free time, they enjoy more favorable affective states as well as better health and well-being (Fritz, Yankelevich, Zarubin, & Barger, 2010; Siltaloppi, Kinnunen, & Feldt, 2009; Sonnentag & Zijlstra, 2006). Moreover, it seems

that psychological detachment from work during leisure time has the potential to alleviate the negative impact of job stressors on health and well-being. There is longitudinal evidence that psychological detachment attenuates the association between quantitative job demands and psychosomatic complaints (Sonnentag, Binnewies, & Mojza, 2010). Future studies might want to explore in greater detail when such a moderator effect occurs and might want to shed more light on the underlying psychological and physiological processes. It would be particularly interesting to directly assess specific resources that are built up by recovery.

Other Factors

In the past, researchers paid attention to the Type A behavior pattern as one important individual difference variable in explaining negative effects of stressful work situations, particularly with respect to cardiovascular diseases. Type A individuals are competitive, hostile, impatient, and hard-driving. Summaries of this earlier research report evidence for a main effect of Type A behavior (particularly the hostility component; Ganster, Schaubroeck, Sime, & Mayes, 1991) on strain (Ganster & Schaubroeck, 1991; Kahn & Byosiere, 1992). In contrast, the evidence for a moderator effect of Type A behavior pattern is weak (Kahn & Byosiere, 1992).

Hardiness is another individual difference variable assumed to moderate the stressor-strain relationship. Hardiness comprises the dimensions commitment, control, and challenges (Kobasa, Maddi, & Kahn, 1982). There is some evidence for a main effect of hardiness on mental health and well-being (Eschleman, Bowling, & Alarcon, 2010), but support for a moderator effect was found only in some studies (e.g., Howard, Cunningham, & Rechner, 1986), but not in others (e.g., Tang & Hammontree, 1992).

Sense of coherence (Antonovsky, 1991) is a concept closely related to hardiness. Its central aspects are perceived comprehensibility, manageability, and meaningfulness of the environment. Again, there is support for a main effect of sense of coherence, but evidence for a buffer effect is mixed (Höge & Büssing, 2004; Hogh & Mikkelsen, 2005; Söderfeldt, Söderfeldt, Ohlson, Theorell, & Jones, 2000).

Conclusions About Moderator Effects

Methodological reasons make it difficult to detect moderator effects, particularly in nonexperimental studies. Moderated regression analysis is a conservative procedure, which makes it hard to establish moderator effects (Shieh,

2009). In addition to methodological reasons, conceptual problems might have contributed to the mixed findings. First, as argued by Cohen and Wills (1985) and extended by de Jonge and Dormann (2006), resources need to match the stressors they should buffer. Organizational and personal factors that are irrelevant for dealing with specific stressors cannot function as moderators. Second, it has to be taken into account that not all potential resources might be equally important for all persons. It might also be that some resources can compensate for the lack of other resources.

If we consider the research evidence in the light of methodological and conceptual problems associated with the test of moderator effects, it seems warranted (and necessary) to continue research in this area. Future studies may want to pay attention to the following issues: First, research should focus on configurations of stressors and resources that match with one another. Second, compensation effects between various resources should be addressed. Third, large sample sizes are needed for ensuring sufficient power for detecting moderator effects. Fourth, design issues are important as well. Given the power issues involved, one can select workplaces with the extremes of stressors (high versus low stressors) and resources (e.g., very high versus very low job control) and test for interactions within such a design (Aiken & West, 1991). Fifth, to overcome potential confounds between job stressors and resources (that might result from employees' active reduction of stressors when they do have adequate resources), newcomers should be studied. Finally, we suggest to combine experimental and field studies to a larger extent, attempting to simulate in the experiment the same types of stressors and resources that are studied in the field.

In summary, research on resources has revealed main effects of resources on health and well-being. This finding implies that the availability of resources is helpful and beneficial in itself and across a wide range of situations. Therefore, it pays off to increase resources. Additionally, there is some—although not unequivocal—evidence that certain resources can attenuate the negative effects of stressors on health and well-being.

Stress and Performance

Stress in organizations may impact not only individual health and well-being but also performance. Performance refers to individuals' actions that are relevant for organizational goals (Campbell, McCloy, Oppler, & Sager, 1993). Borman and Motowidlo (1993) differentiated between task and contextual performance. Task performance refers

to in-role behaviors that contribute to the organization's technical core. Contextual performance refers to extrarole, discretionary behaviors that do not directly contribute to an organization's technical core but are assumed to support its broader organizational, social, and psychological environment; it includes behaviors that support the status quo (e.g., organizational citizenship behaviors [OCBs]) and behaviors that intend to bring about change (Morrison & Phelps, 1999).

There are several contradictory assumptions about how stressors in organizations affect performance. It is plausible to assume that stressors have a negative linear effect on performance. Such a negative effect can be explained by direct and indirect effects. The direct effect implies that stressors, particularly situational constraints, make task accomplishment more difficult, if not impossible. For example, where a task has to be accomplished with specific technical equipment and this equipment is not available because of a computer breakdown, task performance will suffer directly. Moreover, stressors may indirectly affect performance by, for example, decreasing alertness or motivation, which in turn negatively affects performance.

There is a long tradition in conducting laboratory studies on the task performance—effects of stressors (Postman & Bruner, 1948). These studies show that exposure to stressors leads to cognitive reactions such as narrowed attention (including a focus on salient cues) and reduced working memory capacity (Baddeley, 1972; Hamilton, 1982; for summaries, see Hockey, 1986; Wickens, 1996). A reduced working memory capacity is associated with a speed/accuracy trade-off when working under stressful conditions, particularly under time pressure (Hockey, 1986; Lulofs, Wennekens, & van Houtem, 1981). Moreover, narrowed attention and reduced working memory capacity have an impact on decision-making strategies. More specifically, they result in simpler decision strategies, recognitional rather than analytical strategies, and less complete mental simulations (Klein, 1996). Finally, although it is plausible to assume that the effect of stressors on a performance decrease may be mediated by fatigue, empirical studies tend not to support this idea (Ackerman, 2011). Here, individual differences might play a major role (Kanfer, 2011).

Some of these effects of stressors were also found in more realistic simulations of work environments. For example, simulated workload resulted in a performance decrease in some studies (Glaser, Tatum, Nebeker, Sorenson, & Aiello, 1999; Jimmieson & Terry, 1999), although not in all (Shaw & Weekley, 1985). When using a mail-sorting task, Searle et al. (1999) found that high job

demands (i.e., high workload) were associated with an increase in performance attempts, but also with a reduction in performance accuracy, particularly in situations with low control.

It has been suggested that the differentiation between challenge and hindrance stressors is particularly relevant when examining performance effects of stressors. Challenge stressors (e.g., workload, high time pressure) are expected to increase performance, whereas hindrance stressors (e.g., situational constraints, social conflicts) are expected to decrease performance (LePine, Podsakoff, & LePine, 2005). Findings from meta-analyses on this differentiation are mixed. While meta-analyses consistently report negative relations between hindrance stressors and performance (Gilboa, et al., 2008; Le Pine et al., 2005), one meta-analysis reported the expected positive relationship between challenge stressors and performance (Le Pine et al., 2005), whereas the other meta-analysis reported no significant overall relationship between role overload (a typical challenge stressor) and performance (Gilboa et al., 2008); for managers, the relationship was even negative. It might be that challenge stressors unfold their performance-enhancing potential only under specific circumstances, for instance, when social support is high or when situational constraints are absent. Overall, the meta-analysis by Gilboa et al. (2008) clearly demonstrated a negative association between job stressors and job performance. Importantly, for most of the stressors, this negative association was also found when objective performance data or supervisory performance ratings (as opposed to self-report data) were used.

Job stressors may impair not only task performance, but also organizational citizenship behavior (OCB). A recent meta-analysis by Eatough, Chang, Miloslavic, and Johnson (2011) revealed significant negative associations between role ambiguity and role conflict on the one hand and OCB targeted at the individual and OCB targeted at the organization on the other. Again, with respect to role overload the findings were less clear, with zero being included in the confidence intervals for some of the analyses. Interestingly, role ambiguity showed a stronger negative association with task performance than with OCB, and role conflict showed a stronger negative association with OCB than with task performance. This meta-analysis further suggests that low job satisfaction is the mediator between job stressors and low levels of OCB.

However, with respect to more proactive aspects of performance, job stressors seem to be less detrimental. For instance, by using longitudinal and diary data, studies suggested that a high level of job stressors is positively

related to personal initiative (Fay & Sonnentag, 2002; Ohly & Fritz, 2010).

Taken together, findings from field studies tend to demonstrate a negative association between job stressors and some of the core performance indicators (e.g., task performance, OCB), particularly when it comes to stressors that can be classified as *hindrance stressors*. Thus, this more recent research overcomes ambiguities from earlier studies from which no clear conclusions could be drawn (Jackson & Schuler, 1985; Tubbs & Collins, 2000). Nevertheless, it has to be noted that the methodological rigor in research on the stressor–performance relationship lags behind the methodological approaches used in studies on the stressor–health relationship. For instance, longitudinal research is still rare and even third variables that might account for an association between job stressors and poor performance are not always included in the analyses.

Stress and Other Aspects of Organizational Behavior

Job stress is related to counterproductive work behavior, low organizational commitment, high turnover rates and—under specific conditions—increased levels of absenteeism.

Counterproductive work behavior (CWB) refers to behavior that intends to harm other people at work or the organization as a whole; it includes acts of aggression, hostile behavior, theft, sabotage, and other destructive types of behavior. There is empirical evidence that job stressors such as interpersonal conflicts and situational constraints are positively related to acts of CWB, with negative emotions being a core mediator (Fox, Spector & Miles, 2001). Meta-analytic evidence further suggests that interpersonal conflicts tend to be more strongly related to aggression targeted at other individuals, whereas situational constraints tend to be more strongly related to aggression targeted to the organization (Hershcovis et al., 2007).

Organizational commitment refers to an individual's bond or link to the organization (Mowday, Porter, & Steers, 1982). It comprises attitudinal, normative, and continuance aspects (Allen & Meyer, 1990). Two meta-analyses that examined the association between role stressors and organizational commitment reported significant negative correlations between these types of stressors and the three aspects of organizational commitment (Mathieu & Zajac, 1990; Meyer et al., 2002). Thus, individuals perceiving a more stressful work situation reported lower organizational commitment. By building on the

challenge–hindrance framework, a more recent meta-analyses resulted in a somewhat more differentiated pattern of findings: Consistent with the earlier meta-analytical research, hindrance stressors were negatively related to organizational commitment, whereas challenge stressors showed no significant bivariate correlation with organizational commitment, but were a positive predictor of organizational commitment in a meta-analytic path model (Podsakoff et al., 2007).

There is clear meta-analytic evidence that work-related strains as well as poor physical and psychological health are positively related to *absence behavior* (Darr & Johns, 2008; Farrell & Stamm, 1988; Martocchio, Harrison, & Berkson, 2000). However, this does not necessarily imply that job stressors are related to absenteeism. Stressors may overlap with strain and strain may overlap with absenteeism but strain may not be the mediator between stressors and absenteeism. A variance decomposition idea explains how such a relationship may appear. There is common variance between stressors and strain and between strain and absenteeism. But the two common variance fields do not overlap. Thus, it is that part of strain that is not related to stressors that may contribute to absenteeism. As a matter of fact, data on the relationship between stressors and absenteeism are inconclusive. Cross-sectional studies found weak and often nonsignificant relationships between job stressors and absence data (P. Y. Chen & Spector, 1992; Hemingway & Smith, 1999; Peter & Siegrist, 1997). Some studies revealed positive relationships between stressors and absenteeism (e.g., Kristensen, 1991), while others showed negative relationships (e.g., North, Syme, Feeney, Shipley, & Marmot, 1996).

Also longitudinal studies resulted in inconsistent findings. For instance, Tang and Hammontree (1992) found that stressful events in police officers' work were a significant predictor of self-reported absence, also when controlling for prior absence six months before. Vahtera, Kivimäki, Pentti, and Theorell (2000) analyzed absence data from Finnish municipal employees over a period of 7 years. They found that initially healthy employees who experienced high job demands in 1990 had an increased risk of long absence spells (more than 3 days) during subsequent years than employees with low psychological job demands in 1990. The experience of downsizing and perceived job insecurity also increased the risk of absence spells (Kivimäki et al., 1997).

Smulders and Nijhuis (1999) collected data on absence frequency and rate in a Dutch technical maintenance company. When controlling for employee health and

absenteeism in the first year of their study, Smulders and Nijhuis found that high job demands were not associated with higher absence frequency or absence rate during the following three years. Contrary to what one might expect, high demands predicted a *lower* absence rate, particularly when using the Poisson regression method. Similarly, a natural experiment (Parkes, 1982) found lower absence rates in high-demand work settings. A more recent study by Demerouti, Le Blanc, Bakker, Schaufeli, and Hox (2009) found increased presenteeism (i.e., coming to work when being ill) when job demands were high.

These cross-sectional and longitudinal findings suggest that the relationship between job stressors and absenteeism does not follow a simple pattern. First, it might be that the relationship is contingent on moderator variables. In line with the job demand–job control model (Karasek, 1979) one might argue that job control is such a moderator. However, although there is some support for this assumption (e.g., Dwyer & Ganster, 1991), most empirical studies did not confirm the hypothesized interaction effect of job control on the demands–absenteeism relationship (Smulders & Nijhuis, 1999; Vahtera, Pentti, & Uutela, 1996).

Moreover, person factors such as organizational or professional commitment might play a role in the stressor–absenteeism relationship. It might be that in stressful work situations absenteeism increases in employees with low commitment but decreases in highly committed employees. Data reported by Jamal (1984) partially supported this assumption. Gender might also play a role. For example, Melamed et al. (1995) found substantial correlations between objective monotony and sickness absence in women, but not in men.

Additionally, a study by Peter and Siegrist (1997) suggests that it is not the stressfulness of a situation per se that affects an employee's absence behavior. In accordance with the effort–reward–imbalance model, the authors found that status incongruence (i.e., a mismatch between effort and career achievements) was positively related with both short-term and long-term absenteeism in middle managers, while effort alone (i.e., time pressure and interruptions) was not related to absenteeism. These findings can be explained in the context of a psychological contract interpretation (Rousseau, 1995): Stressors increase absenteeism if employees feel that their efforts are not rewarded adequately. A longitudinal study conducted in Denmark suggests that positive features of the work situation (e.g., skill discretion, decision authority, social support, meaning of work) are more powerful in predicting low absenteeism than are low demands (Nielsen et al., 2004).

Stressful work situations might also matter with respect to *turnover intentions and turnover behavior*. There is rather consistent evidence from numerous studies that job stressors are positively related to intentions to quit the organization and to job search behavior (Cavanaugh et al., 2000; P. Y. Chen & Spector, 1992; Gupta & Beehr, 1979). With respect to actual turnover behavior, the meta-analysis by Podsakoff et al. (2007) suggests that mainly hindrance stressors—but not necessarily challenge stressors—are positively related to turnover (see also Griffeth, Hom, & Gaertner, 2000).

Taken together, there is empirical support for the assumption that job stressors are related to workplace aggression and other kinds of counterproductive behavior, to low organizational commitment, turnover intentions, and turnover behavior. However, with respect to organizational commitment and turnover intentions the issue of causality remains unclear. Although it makes intuitive sense to assume that experiencing a stressful work situation increases the intention to quit the organization, individuals who plan to leave the organization might *perceive* more stressors than do their coworkers, who in fact experience the same work situation but intend to stay. Overall, research in this area suggests that organizational stress is not only detrimental for individuals' health and well-being. It can also harm the organization by acts of counterproductive behavior, increased turnover rates, and—at least in some circumstances—increased absenteeism.

STRESS INTERVENTIONS

There are a great variety of interventions that aim at reducing the negative effects of stressors. These interventions may directly address the stressors, and intend to increase resources and to decrease strain. In the broader context, interventions focusing on lifestyle change also may be seen as a part of a stress intervention program.

TABLE 21.3 Stress Interventions in Organizations

	Individual	Organizational
Stressor reduction	Reduction of individual stressor, e.g., time pressure	Reduction of stressor, e.g., organizational problems
Resource increase	Strengthening efficacy beliefs	Participation in decision making; health circles
Strain reduction	Relaxation, stress inoculation, training, respites (vacations, leisure time)	Rest periods
Lifestyle changes	Anti-smoking program; exercise program	No-smoking buildings; salient staircases vs. salient elevators

Table 21.3 gives an overview of these approaches by differentiating between interventions that target the individual versus interventions that target the organization as a whole. While a differentiation in various approaches makes sense in conceptual terms, in many cases multiple approaches are combined, for example, institutional resource enhancement and individual stress-management programs (see Kompier, Aust, Van den Berg, & Siegrist, 2000; Kompier, Cooper, & Geurts, 2000; Semmer, 2006).

Stressor Reduction

Stressors can be reduced by individuals and by the organization (or a combination of both). *Individual stressor reduction* is often a consequence of stress management programs that alert employees to the fact that they can change certain aspects in their work environment. However, individual stressor reduction often presupposes a certain degree of control over work. Certainly, people have an impact on what the job looks like—including the stressors and the resources (Ilgen & Hollenbeck, 1991). For instance, during job crafting efforts (Wrzesniewski & Dutton, 2001), employees may reduce job stressors. Quantitative empirical research on job crafting, however, is still in its infancy (Tims, Bakker, & Derks, in press).

Organizational stressor reduction approaches may take many different forms. Typical examples include a reduction of noise, change of assembly line speed in accordance with the circadian rhythm, or a reduction of interruptions at work. A general stressor reduction approach (or exposure time reduction) is to decrease the number of working hours, which seems to have positive effects, as reported in some company reports (Kompier, Aust, et al., 2000) and in a meta-analysis (Sparks et al., 1997). Other organizational approaches reduce specific stressors that are suspected to be problematic. For example, an organization may assure a better flow of material and, thereby, reduce organizational problems, or thereby may reduce time pressure, task ambiguity, or task difficulty. Swedish researchers reported findings from a study on stressor reduction in urban bus drivers. Typical measures included improved street maintenance, route reconfigurations, and changes in the design of bus stops, resulting in a reduced number of job hassles (Rydstedt, Johansson, & Evans, 1998). Overall, such an organizational stressor reduction approach seems to be useful (see Semmer, 2006), but problems may arise if such an approach is used as a single intervention and without combining it with other approaches: First, reducing stressors may sometimes lead to a reduction of challenges. If

there is high qualitative overload, one may be tempted to reduce overload by decreasing the cognitive demands of a job. This can, however, reduce not only overload but also challenges and resources. Second, because technological and organizational changes are quite frequent and increasingly rapid, research is too slow to tell us which stressors are particularly problematic and need to be taken care of. Therefore, reduction of stressors should be accompanied by an increase in resources.

Increase in Resources

Increase in resources (Demerouti et al., 2001; Hobfoll, 1998) is a popular approach to stress management. These resources can include personal resources and organizational resources such as provided within job design initiatives.

Coping skills, efficacy beliefs, and individual competencies are individual-level resources that could be increased during stress intervention programs. The benefits of increasing coping skills and efficacy beliefs have been demonstrated in evaluation studies (S. Chen, Westman, & Eden, 2009; Gardner, Rose, Mason, Tyler, & Cushway, 2005). Strengthening individual competences, however, has not been typically discussed as a stress prevention technique. However, we think that competence is an important resource in the stress process. First, “working smarter, not harder” is a good description of what excellent performers do (Frese & Zapf, 1994; Sonnentag, 2000); since working smart implies using efficient rather than inefficient action strategies, it should be associated with lower strain levels. Second, it follows from the person–environment fit model that people may increase the fit by developing their skills to deal with environmental demands.

Organizational stress interventions that aim at an increase in job control and an increase employee participation in decision making are promising approaches to reduce the effects of job stress. In a classic study, Wall and Clegg (1981) showed that increase in autonomy and control by introducing semi autonomous work groups led to short- and long-term (12 months after the study was ended) increases in mental health. Restructuring work by increasing job content and responsibilities often has a stress-preventive function as well. Researchers and organizations paid quite a lot of attention to the effects of *institutionally increasing* control (S. E. Jackson, 1983; Wall & Clegg, 1981). Using a four-group Solomon control group design, S. E. Jackson (1983) showed that an increase

of participation in decision making decreased emotional stress, absence frequency, and turnover intention. More recent studies provided interesting additional insights. DeJoy and his coworkers (2010) evaluated the effects of a participatory process during difficult economic times. Overall, they did not find large increases in positive outcomes in the intervention group; however, when comparing the outcomes in the intervention group with findings in the control groups, it became obvious that the participatory effects buffered the negative effects of the adverse economic environment. Holman, Axtell, Sprigg, Totterdell, and Wall (2010) demonstrated that it is not the participation per se that accounts for the positive outcomes of participative intervention, but changes in job characteristics such as job control, skill utilization, and feedback that increased as a result of the participation process.

An additional important resource is social support. Studies have shown that social support may increase during job stress interventions (Le Blanc, Hox, Schaufeli, Taris, & Peeters, 2007) and that increase in job control is particularly beneficial in a situation where supervisor support is high (Frese, 1999; Logan & Ganster, 2005).

Successful stress interventions often combine a reduction of job stressors with an increase in resources. For instance, Bunce and West (1996) showed that encouraging people to innovatively deal with work stressors led to a reduction of strain (this finding was replicated by Bond & Bunce, 2000). Bunce and West’s concept increased the subjective resources to deal with stressors because it encouraged innovative approaches. Such a focus on innovation is similar to the German concept of health circles (quality circles applied to health issues) in which employees discuss stressors and work problems that can potentially lead to ill health (Aust & Ducki, 2004; Beermann, Kuhn, & Kompier, 1999). Van Dierendonck, Schaufeli, and Buunk (1998) proposed a program to reduce burnout with a similar element of suggesting innovative approaches to deal with the stressors. They combined their approach to changing the workplace with enhancing the individual’s “realistic” orientation toward investments and outcomes so that the impression of equity was increased. Van Dierendonck et al. found that their training reduced emotional exhaustion, although it did not positively affect depersonalization and personal accomplishment. Searle (2008) conducted an experiment that emphasized the importance of an active approach as well. In this study, a program that increased personal initiative decreased ill health. However, the effect was not due to changes in personal initiative, which he describes as a method problem of measurement.

Strain Reduction

Individually oriented strain reduction programs belong to the most frequently used programs. A large body of studies exists and reviews find clear and positive effects. Stress management programs attempt to influence employees to interpret a situation not as stressful but as a challenge. They also teach how to improve one's coping strategies and to reduce strain, for instance, by stress immunization or relaxation techniques. Since there are excellent reviews (e.g., Bamberg & Busch, 1996; Murphy, 1996; Van der Klink, Blonk, Schene, & Van Dijk, 2001), we do not need to discuss studies on stress management in detail.

Two techniques have been used extensively (Murphy, 1996): relaxation techniques and cognitive-behavioral techniques (see also Bellarosa & Chen, 1997). Relaxation is often based on progressive muscle relaxation (Jacobson, 1938) as well as on meditation and biofeedback. By and large, progressive muscle relaxation has been shown to be effective (e.g., Murphy, 1996; Richardson & Rothstein, 2008). A recent study has shown that the positive effects of relaxation can be achieved after relatively short relaxation periods, making this intervention highly applicable in organizations (Ponce et al., 2008). Other relaxation and meditation techniques, including those that use a mindfulness approach (Fredrickson, Cohn, Coffey, Pek, & Finkel, 2008), have been shown to be successful in organizational settings (Flaxman & Bond, 2010).

Cognitive-behavioral techniques are based on cognitive therapy for depression (Beck, 1967; Whisman, 1998), on Rational-Emotive Therapy (Ellis, 1962), and on stress immunization or stress inoculation (Meichenbaum, 1985). Cognitive therapy has been shown to be a highly useful procedure for treating depression in clinical trials (Robinson, Berman, & Neimeyer, 1990) and in stress management for working populations (Bamberg & Busch, 1996; Murphy, 1996; van der Klink et al., 2001). Most studies do not really differentiate in detail between cognitive and Rational-Emotive Therapy and a combination is usually preferred. Similar positive effects appear for Rational-Emotive Therapy. Rational-Emotive Therapy works by helping the person to use rational self-instructions. For example, a person might have a tendency to exaggerate a given stress situation and catastrophize when something goes wrong. Alternative self-instructions are then taught (e.g., it is not catastrophic if something goes wrong, because mistakes happen to most people). Stress inoculation training is "designed to impart skills to enhance resistance to stress" and its objective is "to prepare the individual to respond more favorably to negative stress events"

(Saunders, Driskell, Johnston, & Salas, 1996, p. 171). Stress inoculation includes three intervention phases: first, conceptualization and education, second, skill acquisition and rehearsal, and, third, application and follow-through (Saunders et al., 1996). The first phase, conceptualization and education, teaches people to have a more sophisticated view of the nature of stress. The second phase, acquisition and rehearsal, provides a stronger repertoire of coping skills and rehearses them either *in vivo* (e.g., role-play) or in guided imagery. The third phase, application and follow-through, works also via role play and guided imagery to deal with the real-life threats and stressors. A meta-analysis summarizing 37 studies showed stress inoculation affected performance anxiety ($r = 0.51$), state anxiety ($r = 0.37$), and also performance ($r = 0.30$) (Saunders et al., 1996).

Several meta-analyses have been published that cover a broader range of stress-management studies. For instance, Bamberg and Busch (1996) included 16 studies on work-related stress management and found an average effect size of $d = 0.41$. A second meta-analysis (Van der Klink et al., 2001) found somewhat different effect sizes for 18 cognitive-behavioral studies ($d = 0.68$), 17 relaxation studies ($d = 0.35$), and 8 so-called multimodel approaches (acquisition of passive and active coping skills) ($d = 0.51$). Finally, a more recent meta-analysis (Richardson & Rothstein, 2008) reported also the highest effect sizes for cognitive-behavioral interventions ($k = 7$ studies; $d = 1.16$). For the 17 relaxation studies ($d = 0.50$) and the 19 multimodel studies ($d = 0.24$), the effect sizes were somewhat lower. Overall, this pattern of findings suggests that cognitive-behavioral programs are a powerful intervention method. Effect sizes for relaxation programs are lower, but still substantial. Interestingly, an additional moderator analysis in Richardson and Rothstein's meta-analysis suggests that more is not always better: Programs that comprised three or more treatment components tended to have lower effect sizes than programs focusing on one or two treatment components. This finding might also explain why multimodal training is not necessarily better (and often less effective) than training that focuses on a cognitive-behavioral intervention as a single approach. It might be that programs with one or two clearly identified components give participants a better orientation as to how to address job stress than do programs with multiple components, which might even confuse participants.

Overall, stress management programs increase health by about one half of a standard deviation. Interestingly, Murphy (1996) and van der Klink et al. (2001) reported that results were stronger for more "impaired" individuals

and for remedial interventions than for normal employees or preventive approaches. This implies that clinical studies show better results than stress management trainings for unselected working populations. An additional constraint of most stress management programs is that they presuppose that the employees can actually do something about their stress level (i.e., have at least some measure of control at work). Employees with a high degree of job control and with higher status jobs showed better success of stress management interventions than low-control/low-status-job employees (van der Klink, et al., 2001). For this reason, stress management programs are probably less useful for blue-collar workers than for white-collar workers and managers.

Thus, in general, a positive picture on stress management programs appears. However, a number of caveats are in order: First, it is quite plausible that negative or zero effects do not find their way into the journals (Murphy, 1996). Second, the better studies with randomized control groups showed a lower degree of success than the studies without a control group (Murphy, 1996). Finally, reviews report non specific effects; this result highlights the importance of using control groups in stress intervention studies. For these reasons, a certain degree of skepticism has to prevail. On the positive side, stress management programs are often effective to increase life expectancy, for example, if given to heart disease patients (34% reduction in cardiac mortality; Dusseldorp, Van Elderen, Maes, Meulman, & Kraaij, 1999).

An *organizational approach* to reducing strain is to provide rest periods. While stress management is a modern topic, the study of rest periods is a more traditional one. Over a long period, only a few studies had been published per year (Graf, Rutenfranz, & Ulich, 1970). It is well known that recovery is fastest after short periods of work and that the first few minutes of a rest period are most important for recovery. Graf et al. (1970) suggested, therefore, that 5% of the work time should be taken as rest periods. Performance is higher when employees anticipate rest periods (Graf et al., 1970). Therefore, there is usually no decrement in overall performance in spite of the time needed for rest periods (Galinsky, Swanson, Sauter, Hurrell, & Schleifer, 2000; Graf et al., 1970). At the same time, stress effects are smaller when rest periods are interspersed in work (Galinsky et al., 2000). There is evidence in the literature that rest periods should be organizationally prescribed and monitored because people tend to take less frequent and too short rest periods when left to their own decisions (Graf et al., 1970; Henning, Sauter, Salvendy, & Krieg, 1989).

Recently, interest in rest periods is increasing. Importantly, this research has shown that the types of activities employees pursue during the rest period play a role in subsequent strain reduction (Trougakos, Beal, Green, & Weiss, 2008). Organizations could support rest activities such as relaxation, meditation, or even napping by providing “silent rooms” (Krajewski, Wieland, & Sauerland, 2010).

Lifestyle Changes

Individually oriented lifestyle change programs attempt to improve diet, support healthy living (e.g., by reducing alcohol and tobacco consumption), and encourage physical exercise. Employee assistance programs (EAPs) often target alcoholism or other types of addiction, but they can also include exercise and stress management programs; they showed a tremendous growth in companies during the 1970s and 1980s (Matteson & Ivancevich, 1987). Breslow and Enstrom (1980) found that men who used seven positive habits (sleeping seven to eight hours, eating breakfast almost every day, never or rarely eating between meals, being near height-adjusted weight, never smoking, drinking almost no alcohol, and engaging in regular physical activity) had a lower mortality rate across 10 years than those who followed none to three practices. Exercise and health-promoting programs at work have been quite successful in decreasing anxiety (Long & Van Stavel, 1995), in reducing cardiovascular mortality after myocardial infarction (O'Connor et al., 1989), and in enhancing general well-being (Ivancevich & Matteson, 1988). A recent meta-analysis demonstrated that, overall, workplace interventions targeting physical activity were positively associated with increased fitness, better mood, and some physiological indicators (Conn, Hafdahl, Cooper, Brown, & Lusk, 2009). However, effect sizes varied largely from study to study, suggesting that specific characteristics of the interventions and individual characteristics might play a role in the effectiveness of such programs.

Surprisingly, *organizational approaches*, such as architecture of (office) buildings, have not been studied extensively as potential stress interventions. Office buildings may make it easier or harder to use the stairs, for example, by making either the staircase or the lift salient. It is surprising that a relatively small amount of daily physical activities, such as walking stairs, walking or cycling to work, or doing small errands on foot, have a substantial effect on mortality ratios. An example is the classic study by Paffenbarger, Hyde, Wing, and Hsieh (1986) that

showed that men burning 500 to 2,000 kcal per week through physical exercise had a reduced mortality rate within the 16 years of study in comparison to men who did not do any physical exercises. The reduced mortality rate was even more pronounced for those burning 2,000 kcal per week. Burning 2,000 kcal per week is equivalent to walking, for example, 35 km per week or climbing three flights of stairs 70 times per week. This result speaks for the importance of encouraging light sports in the office building by designing and constructing adequate, aesthetic, and salient staircases and by encouraging employees to use the stairs. However, motivating people to take the stairs is relatively difficult; interventions that aim at an increase in walking or active travel (e.g., cycling) seem to be more successful (Dugdill, Brettle, Hulme, McCluskey, & Long, 2008).

Further suggestions for organizational interventions that may contribute to stress management come from environmental psychology. Studies have shown that spending time in natural environments increases mood and restores attention in comparison to time spent in urban environments (Berman, Jonides, & Kaplan, 2008; Hartig, Evans, Jamner, Davis, & Gärling, 2003). Thus, organizations may opt for designing natural recreation areas that can be visited during work breaks (e.g., gardens, naturally enriched courtyards).

Conclusions on Stress Interventions

Taken together, the literature on stress interventions suggests a number of conclusions. First, stress intervention studies go under very different names and are presented in very different disciplines and journals. We think that it will pay off to pull these diverse areas together and integrate theories across different intervention domains. The best developed areas of stress interventions refer to stress management techniques, lifestyle changes, and rest periods (although part of the literature in this area is quite old). These areas can be studied experimentally and only imply change at the level of the individual. Organizational approaches have been studied much less frequently because they are more difficult to investigate; there is a need to look at moderators (e.g., how well is the program supported by management and how well is it implemented) and these studies are much more risky because many aspects cannot be controlled (Biron, Gatrell, & Cooper, 2010).

Second, nearly every review of the field speaks about the importance of doing more studies in the area of organizational change. We can only repeat this call. Most authors assume that it makes sense to combine structural and

institutional changes with individually oriented approaches (e.g., Bamberg & Busch, 1996; Ivancevich, Matteson, Freedman, & Phillips, 1990; Kompier, Cooper, et al., 2000; Murphy, 1996). Third, practically every review on stress intervention techniques has called for better designed studies in this area. Since there seems to be a relationship between effect of study and its design (Murphy, 1996), this issue needs to be taken seriously. Undoubtedly, during the past 2 or 3 decades, research methodology has improved, particularly in the area of stress management and life style changes. Fourth, one issue of improving design is related to the fact that there are nonspecific effects of stress management. A no-treatment control group does not actually account for unspecific effects; it is, therefore, necessary to include pseudo-treatment control into designs because purely thinking about stress at work and self-reflecting may actually enhance health outcomes as well. Fifth, most studies look only at short-term changes, whereas we need to be able to produce long-term changes with stress interventions.

Sixth, by and large, more process-oriented research on stress interventions needs to be done (Bunce, 1997). This can be done by developing manuals, and checking how much trainers conform to the theoretically proposed procedures, how much of the effect was due to the specific program, and how much it was due to general effects. Good examples for such an approach exist within clinical psychology (e.g., Castonguay, Hayes, Goldfried, & DeRubeis, 1995; Hollon, DeRubeis, & Evans, 1987; DeRubeis et al., 1990). Finally, more research is needed that pits different approaches against each other. One of the most important issues is whether there are general and specific effects of an intervention (Bunce, 1997; Murphy, 1996). Trainer characteristics also need to get more attention in empirical studies.

OVERALL CONCLUSIONS

Research summarized in this chapter shows that organizational stress has detrimental effects on individual health and well-being. Moreover, stress interventions, particularly those aiming at individual stress management, have been found to be beneficial.

Researchers have criticized past empirical studies on organizational stress for their methodological shortcomings (Frese & Zapf, 1988; Kasl, 1978; Sullivan & Bhagat, 1992). During the past 2 decades, an increasing number of studies followed a more rigorous research methodology (e.g., objective measures of stressors, test of curvilinear

effects, and particularly the widespread use of longitudinal designs). We are convinced that this improved methodology has contributed to substantial progress within organizational stress research. Specifically, we observed progress with respect to the following issues:

First, objective stressors—and not just the perception of stressors—are related to indicators of poor health and well-being. This implies that the well-documented empirical relationship between stressors and strains cannot be fully explained by common method variance and overlap in content between stressors and strain variables.

Second, stressors seem to have a causal effect on health and well-being. The exposure to job stressors predicts an increase in strain levels over time. There are *additional* reverse effects of strains on stressors. However, they seem to be relatively weak.

Third, resources are important for an individual's health and well-being. The main effects of resources such as job control, social support, and core self-evaluations are stronger than their buffer effects.

Fourth, better designed studies with objective measures report smaller correlations than studies with subjective measures (cf. also Zapf et al., 1996). It may appear that this points to actually low impact rates of stressors on strain and that the effect of stressors at work is rather small. We think that this conclusion would be misleading (Frese & Zapf, 1988) because (a) no study ever measures all job stressors; (b) objective measures of stressors underestimate the relationship between stressors and strains because observers' errors decrease the correlations; (c) strain is caused by many factors (job stressors, biological and psychological predisposition, stressors outside work, etc.)—every one of them can only have a certain amount of influence; (d) there is a selection effect in most studies on stress at work because ill people have a lower probability to be in the sample (healthy-workers effect); (e) there are moderators that may buffer the relationships; and (f) relatively low correlations are of practical importance.

As a whole, the advancements in organizational stress research demonstrate that it pays to invest in a better research methodology. However, to make real progress in a field it is not sufficient to focus only on research methodology. It is necessary to also invest in theory development and to make sure to address the most relevant research questions (Brief & George, 1995). For deepening the understanding of the process of how and when organizational stress impacts the individual and the larger organization we suggest the following avenues for future research:

First, there is a clear need for a direct comparison between competing theoretical models. Such comparisons are still very rare (cf. for an exception, de Jonge, Bosma, Peter, & Siegrist, 2000). Such comparisons will be helpful for advancing theory about organizational stress because they will show which specific assumptions within one model make it superior to a competing model.

Second, researchers should pay more attention to the impact of specific stressors and specific resources on specific strains. Such a specificity hypothesis (Broadbent, 1985) implies that specific stressors are related to specific symptoms, but not to others. Empirical tests of this hypothesis are still rare (Hesketh & Shouksmith, 1986; Steen, Firth, & Bond, 1998). For a resource to be effective as a stress buffer it is crucial that the resource matches the specific requirements of the stressor (Cohen & Wills, 1985; Daniels & de Jonge, 2010).

Third, aspects of time should be taken much more seriously within organizational stress research. When studying the effects of stressors longitudinally, researchers should pay more attention to the time lags between the first and subsequent measurement points. Until now it seems that the time lags have been chosen rather arbitrarily or for convenience reasons. As the Dormann and Zapf (1999) study illustrated, some effects are found only for a limited set of time lags. Also our review of longitudinal studies demonstrated that effect sizes differ between studies using different time lags. Researchers need to spell out more clearly within which time frame they expect specific strain symptoms to develop. Frese and Zapf (1988) have differentiated the following models based on time and stress exposure effects: (a) stress reaction model: implies an ill-health reaction to the stressor, which is reduced when the stressor is reduced; (b) accumulation model: the effect is not reduced even if the stressor no longer present; (c) dynamic accumulation model: the effects increase ill-health further even when individuals are no longer exposed to the stressors; (d) adjustment model: people learn to cope with the stressor and ill-health is reduced even though they are still exposed to the stressors; (e) sleeper effect model: the ill-health appears after the stressor disappears as in the case of posttraumatic stress disorder. Garst et al. (2000) have demonstrated that it is useful to explicitly test different models taking into consideration exposure time and differential timing effects.

Fourth, more attention to time aspects is also necessary when testing interaction effects. It is necessary to examine in more detail at which point in time in the stress process resources are most helpful. For example, resources might act as powerful stress buffers only early in the stress process.

Fifth, researchers should explicitly address the mediating processes in the stressor-strain relationship. This refers both to mediators at the physiological level and to mediators at the emotional and cognitive level (i.e., appraisals).

Sixth, there should be more studies on stress and performance. Laboratory studies suggest that stressors have a negative effect on basic cognitive processes. However, in field study settings, the effects of stressors on job performance are less obvious. It seems that individuals uphold their performance by increasing effort. This increased work effort might have detrimental long-term effects on health and well-being, however. Research on the health effects of organizational stress and research on the performance effects of organizational stress are rather separate research areas, particularly in field studies. By focusing exclusively on health and well-being or on performance effects, researchers get to know only one side of the coin. We suggest to further advance organizational stress research by looking simultaneously at the impact of stressors on performance and health and well-being. Such studies could identify the health and well-being costs of upholding high performance in stressful situations (see Hockey, 1997). Moreover, such studies could shed light on the performance requirements under which strain symptoms occur. It is also useful to address the role of resources by examining which resources let people uphold performance without impairing health and well-being.

Taken together, organizational stress research has benefited from methodologically more sophisticated studies. It has become obvious that organizational stress affects individual health and well-being in a negative way. Individuals, however, have multiple ways of dealing with stress so that neither their health nor their performance suffer necessarily. Despite progress there remain many questions to be answered by future research.

Careers evolve over time (Greenhaus, Callanan, & Godshalk, 2010). Careers are also a product of the times, influenced by the economic, political, cultural, and interpersonal environments in which they are embedded. Recent changes in the global economy have had dramatic effects on work organizations' structure and processes (Greenhaus, Callanan, & DiRenzo, 2008; Sullivan & Baruch, 2009). Moreover, these changes in work organizations have had implications for the manner in which individuals enact careers over the life course (Sullivan & Baruch, 2009).

In this chapter, we first discuss changes in the world of work, focusing on the turbulence of the contemporary economy (DiRenzo & Greenhaus, 2011), the resultant movement toward a more market-driven approach to managing human resources (Cappelli, 1999) that has produced changes in the traditional psychological contract between employers and employees (Rousseau, 1995), and the implications of these trends for the meaning of a career. We then examine theory and research in five specific areas that are critical to understanding contemporary careers—career success, mentoring, career development, international careers, and entrepreneurial careers—and provide suggestions for future research in each area.

The review of the literature is selective in several respects. First, given the nature of this *Handbook*, we adopt a psychological focus on individuals' careers and avoid extensive discussion of career systems at the organizational level as well as sociological perspectives on careers. Second, we do not dwell extensively on topics that are treated elsewhere in this volume, such as diversity

(Hebl & Avery), recruitment (Rynes-Weller & Darnold), job transitions (Feldman & Ng), and withdrawal behavior (Harrison & Newman), with two exceptions. First, although there is a separate chapter on globalism and cross-cultural issues (Bartram), we examine international careers because of their prominence in a global economy. Second, despite a comprehensive chapter on work–life balance in this volume (Allen), we periodically inject family and gender-related issues in some sections because of the connections of gender and family life with many aspects of contemporary careers (Mainiero & Sullivan, 2006).

THE CHANGING LANDSCAPE OF WORK AND CAREERS

Contemporary careers are pursued in an economic environment that is increasingly turbulent (DiRenzo & Greenhaus, 2011). The technologically driven, global, and highly competitive business environment spurred by the 1981–1982 recession has produced fundamental changes in organizational structures and processes. These pressures have encouraged organizations to discard poorly performing business, outsource less central functions, and partner with other organizations to acquire new capabilities that could serve them well in future ventures (Cappelli, 1999).

In order to remain flexible and cost efficient in the face of rapid changes in technology and market pressures and opportunities (Arthur, Inkson, & Pringle, 1999),

organizations have been increasingly reluctant to nurture long-term relationships with employees, instead turning to the external labor market to acquire new capabilities (DiRenzo & Greenhaus, 2011). Organizations' desire to remain flexible has produced changes in the psychological contract between employers and employees, reducing employers' emphasis on a long-term relational focus in favor of a short-term transactional emphasis (Herriot, Manning, & Kidd, 1997; Smithson & Lewis, 2000). Breaches of psychological contracts, including relational contracts (Jensen, Opland, & Ryan, 2010), can have negative effects on a variety of employee work outcomes (Bal, De Lange, Jansen, & Van Der Velde, 2008; Ng, Feldman, & Lam, 2010; Zhao, Wayne, Glibkowski, & Bravo, 2007).

Perhaps the most palpable consequence of economic turbulence and organizations' increased emphasis on short-term commitments has been the heightened loss of jobs (Brown, Haltiwanger, & Lane, 2006; Ho, 2009; Uchitelle, 2006) accompanied by diminished feelings of job security (Kalleberg, 2009; Smith, 2010). The literature has pointed to a growing pessimism in employee perceptions of security (Bansak & Raphael, 2006; Farber, 2005; Fullerton & Wallace, 2007; Kalleberg, 2009) providing support for the notion that the economy has entered "a post-job-security era" in the United States (Tulgan, 2000) and other parts of the world (Herriot et al., 1997; Smithson & Lewis, 2000). The threat of job loss, in conjunction with the flattening of organizational structures, has left employees with fewer opportunities for continuous vertical mobility within their current organization, long a trademark of success in a traditional organizational career (Arthur & Rousseau, 1996).

We suggest that organizations' efforts to remain competitive in the face of extensive economic pressures have influenced the ways in which individuals construe and enact their career. In particular, the prominence of the boundaryless career concept over the past several decades (Arthur et al., 1999) and the renewed interest (Briscoe, 2006) in the protean career (Hall, 1976) have their roots in an era that places a premium on individual employability (DiRenzo & Greenhaus, 2011) and the search for personally meaningful work. We now turn to a discussion of the meaning of a career in the contemporary world.

THE MEANING OF A CAREER

The everyday meaning of a career in the latter half of the twentieth century reflected a number of themes revolving around advancement or vertical mobility, pursuit of a

profession, and stability in one's occupation (Greenhaus et al., 2010; Hall, 1976). These themes limited our understanding of a career because they confined the concept to a small segment of society—managers or professionals advancing in a clearly recognizable path—and restricted the kinds of research questions that could be posed. A pioneering break from these constraints was provided by Hall (1976), who defined a career as "the individually-perceived sequence of attitudes and behaviors associated with work-related experiences and activities over the span of a person's life" (p. 4). Similarly broad definitions quickly followed in the literature. These definitions not only imply that everyone (not only managers or professionals on a fast track) has a work career, but they also legitimize the study of individual perceptions and attitudes regarding a career, what Hughes (1958) referred to as the subjective career.

Several important conceptualizations of a career have emerged in the past several decades that are consistent with the contemporary economic environment. First, a number of researchers, most prominently Arthur and colleagues (Arthur, 1994; Arthur & Rousseau, 1996; Arthur et al., 1999), have concluded that careers are increasingly "boundaryless" in the sense that they represent "independence from, rather than dependence on, traditional organizational career arrangements" (Arthur & Rousseau, 1996, p. 6). Although the literature often equates boundaryless careers with extensive interorganizational mobility, Arthur and Rousseau (1996) recognized that movement across the boundaries of separate employers is only one way in which a career can be boundaryless and identified five additional ways in which careers can be independent from traditional organizational career arrangements, namely where individuals: (a) draw their validation and marketability from *outside* (rather than inside) the present employer; (b) are sustained by *external* (rather than intra-organizational) social networks; (c) engage in *nontraditional* (e.g., horizontal, downward) mobility within a single organization; (d) reject career opportunities for *personal or family* (as opposed to exclusively work-related) reasons; and (e) perceive their career as being boundaryless even in the absence of actual mobility. Each form of a boundaryless career involves crossing physical or psychological boundaries (Inkson, 2006) that are not characteristic of traditional, linear organizational careers.

Arthur et al. (1999) also identified three types of career competencies individuals accumulate from their varied work experiences that can be particularly useful in enacting boundaryless careers; knowing-why, knowing-how, and knowing-whom competencies. Knowing-why

competencies include self-awareness and personal identity that provide motivation and guidance to a career. Knowing-how competencies are the portable skills and knowledge that individuals can transfer to different employment settings. Knowing-whom competencies refer to networks of relationships that produce social capital from which information, guidance, and contacts can flow. It is noteworthy that each career competency extends beyond the confines of one's current employer, for example: knowing-why identification with one's profession rather than one's organization, knowing-how competencies that are transferred from one organization to another, and knowing-whom competencies that are extensively derived from relationships outside the current organization. Recent research has revealed that the greater the boundarylessness of a career the more extensive the accumulation of knowing-why and knowing-how competencies (Colakoglu, 2011).

Despite the appeal of viewing careers as increasingly boundaryless, Greenhaus et al. (2008) identified a number of ambiguities in the meaning of a boundaryless career. First, it is unclear whether career boundarylessness should be conceptualized as a categorical or a continuous variable. Although much of the early literature implies that a career either is boundaryless or it is organizational, scholars have recently considered the boundarylessness of a career to be a matter of degree (Briscoe & Hall, 2006; Colakoglu, 2011; Sullivan & Arthur, 2006). Second, in light of Arthur and Rousseau's (1996) six different forms or emphases of boundaryless careers, it is reasonable to ask whether each element should be weighted equally in determining the boundarylessness of a career. Moreover, Sullivan and Arthur's (2006) view that psychological mobility (the perceived capacity to cross boundaries) is as important an element of a boundaryless career as actual job mobility raises the question of whether *any* mobility is required to consider a career boundaryless. We believe that these kinds of issues require additional attention and some degree of consensus for future research on boundaryless careers to have maximum impact.

There has also been a reemergence of the concept of a protean career introduced into the literature by Hall (1976) more than 35 years ago. His original characterization of a protean career ("... a process which the person, not the organization, is managing... consists of all the person's varied experiences in education, training, work in several organizations... is *not* what happens to the person in any one organization" (Hall, 1976, p. 201) seemed remarkably consistent with the notion of a boundaryless career. Named for Proteus, the Greek god who could change

shape at will, a protean career is under the control of the individual—not the organization—and its aim is the pursuit of psychological success through continuous learning and identity change (Hall, 1976, 1996).

In recent years, the protean concept has shifted from being seen as a structural characteristic of a career to an individual's psychological orientation regarding his or her career (Inkson, 2006; Sullivan & Baruch, 2009). A protean career orientation (PCO) is currently viewed as having two dimensions: (a) self-directed and (b) values-driven (Briscoe, 2006). The self-directed dimension refers to feeling responsible for managing one's career and proactively exploring options and making career decisions as opposed to wanting or expecting an employer to direct one's career. The values-driven dimension refers to striving to meet personally meaningful values and goals rather than values and goals encouraged or imposed by organizations, family, or the larger society. Briscoe, Hall, & DeMuth's (2006) factor analysis of their "Protean Attitude Scale" provides support for the two dimensions of a PCO.

In an attempt to integrate the major themes that run through the boundaryless and protean career literatures, Greenhaus et al. (2008) proposed a "boundaryless perspective" consisting of four components: (1) nontraditional mobility patterns that depart from a continuous, linear career pattern such as job crafting, employment gaps, interorganizational mobility, and nonhierarchical intraorganizational mobility; (2) knowing-why, knowing-how, and knowing-whom career competencies; (3) self-directed and values-driven dimensions of a protean career orientation; and (4) career outcomes. They proposed that career competencies and PCO influence—and are influenced by—nontraditional mobility patterns and suggested that the positive effects of nontraditional mobility on career outcomes are strengthened by extensive career competencies (that enable individuals to identify and succeed in boundary-crossing activities that are relevant to their career aspirations) and by a strong PCO (that encourages the proactive pursuit of personally meaningful values and goals).

Other efforts to identify emerging career forms, as noted by Sullivan and Baruch (2009), include Peiperl and Baruch's (1997) self-directed, boundary-crossing "post-corporate" career, Briscoe and Hall's (2006) 16-cell career typology based on low and high levels of protean (self-directed and values-driven) and boundaryless (psychological and physical mobility) career features, and hybrid careers that contain elements of traditional and nontraditional attitudes and mobility patterns (Granrose & Bacchili, 2006). In addition, the kaleidoscope career model

(Mainiero & Sullivan, 2006) proposes that just as patterns in a kaleidoscope change when the tube is rotated, so too are there changes over the life course in the priority of three criteria that individuals use to make career decisions: authenticity, life balance, and challenge (Sullivan & Baruch, 2009).

Gender and the Meaning of a Career

Do women and men construe and enact their careers in similar ways? Although it has been suggested that women are more likely than men to prefer self-designed careers (Mainiero & Sullivan, 2005; Sullivan, Carden, & Martin, 1998), the limited research has been inconclusive. For example, there does not seem to be a relationship between employee sex and protean career attitudes (Briscoe & Finkelstein, 2009; Briscoe et al., 2006; Ng, Burke, & Fiksenbaum, 2008; Vigoda-Gadot & Grimland, 2008), nor has sex been consistently related to preferred or actual interorganizational mobility (Briscoe & Finkelstein, 2009; Reitman & Schner, 2003; Valcour & Tolbert, 2003).

However, the differences between how women and men construe or enact their career are likely to be more complicated than the mere presence of main effects of sex on mobility patterns or protean attitudes. For example, Mainiero and Sullivan (2006) suggest that women's relational orientation encourages them to view their career in a more complex, holistic manner and to base career decisions, at least in part, on the consequences that these decisions have for other people in their lives, a notion that has been supported in the literature (Mainiero & Sullivan, 2005; Powell & Greenhaus, 2010; Reitman & Schner, 2003; Valcour & Tolbert, 2003). To the extent to which careers are construed in different ways for men (agentic) and women (communal), the meaning of career success is likely to differ as well, a point to which we return in the next section.

CAREER SUCCESS

The question "what makes a career successful" is comprised of two questions: (a) What does it mean for a career to be considered successful? and (b) What are the antecedent factors that contribute to the success of a career? In this section, we first consider the meaning of career success and then discuss its antecedents.

The Meaning of Career Success

Career success has been defined by different researchers as "the accomplishment of desirable work-related outcomes

in any point in a person's work experiences over time" (Arthur, Khapova, & Wilderom, 2005, p. 179), "the positive psychological or work-related outcomes or achievements one has accumulated as a result of one's work experiences" (Judge, Cable, Boudreau, & Bretz, 1995, p. 486), and "the positive material and psychological outcomes resulting from one's work-related activities and experiences" (Seibert, 2006, p. 148). These definitions distinguish work-related or material accomplishments from psychological accomplishments, which is consistent with Hughes's (1958) distinction between the directly observable and measurable objective career and the personally experienced and individually perceived subjective career (Heslin, 2005) laying the foundation for the widespread distinction in the literature between objective and subjective career success.

Objective career success is measured by externally verifiable accomplishments (Heslin, 2005) that are thought to reflect the "shared social understanding" (Arthur et al., 2005) of success by a referent group. The three most frequently examined indicators of objective career success—salary, promotions or advancement, and occupational status or job level (Judge & Kammeyer-Mueller, 2007)—are viable reflections of objective career success to the extent that there is a shared social understanding that these three accomplishments reflect particularly notable achievements. Yet even if money, advancement, and status are consensually viewed as indicators of success, an exclusive reliance on these three indicators presents an incomplete picture of objective career success in those contexts in which their attainment is not feasible (e.g., promotions in a flat organization) or in which other objective indicators (e.g., the learning accomplishments of teachers' students) are more relevant (Arthur et al., 2005; Heslin, 2005).

Subjective career success is the personal appraisal of one's career accomplishments, thereby reflecting an individual's unique understanding rather than a shared social understanding of the importance of different career dimensions (Arthur et al., 2005). The subjective perspective recognizes that individuals show considerable variation in what they value in a career and therefore in what factors they consider in gauging the success of their career. However, the most frequently used indicator of subjective career success, career satisfaction, is not without critics because its measures can include items on career dimensions (e.g., advancement) that may not be relevant to everyone in the sample and omit items on other career dimensions (e.g., interesting work) that are relevant to a segment of a sample (Arthur et al., 2005; Heslin, 2005).

These flaws in the assessment of objective and subjective career success notwithstanding, a rich empirical literature has emerged on the antecedents of objective and subjective career success.

The Antecedents of Career Success

Although researchers have used somewhat different terminology to categorize antecedents, we adopt the four categories used by Ng, Eby, Sorensen, and Feldman (2005) in their meta-analytic examination of the predictors of career success: human capital investments, organizational sponsorship, stable individual difference variables, and demographic characteristics. Three conclusions can be drawn from the meta-analysis and the broader literature: (1) all four categories of antecedents are associated with career success, although they may be differentially related to objective and subjective indicators of success; (2) many relationships predicting success are likely to be moderated by situational characteristics and/or personal variables; and (3) the interplay between employee sex and career success is linked to men's and women's participation in—and orientation toward—their family role.

Categories of Antecedents

There is substantial support for the positive impact of *human capital investments* on career success. These investments include a strong work identity, long work hours, education, extensive tenure and work experience (including international experience), participation in career planning activities, acquisition of knowledge and skills, and job competence. Ng et al. (2005) found that virtually all of the human capital variables they examined were more strongly related to objective success (salary or promotions) than to subjective success (career satisfaction).

Organizational sponsorship variables, which include career sponsorship, supervisor support, opportunities for training and development, and organizational resources, were related to objective and subjective career success, although they were generally more strongly related to subjective than objective indicators (Ng et al., 2005). Although Ng and colleagues did not isolate mentoring from other sources of sponsorship, mentoring has played such an important role in career success (Allen, Eby, Poteet, Lentz, & Lima, 2004) that it is treated in more detail in a subsequent section of this chapter.

Ng et al. (2005) included eight stable individual difference antecedents in their meta-analysis. Their findings revealed that conscientiousness, extroversion, and proactivity are positively related—and neuroticism is

negatively related—to objective and subjective success, agreeableness is negatively related to objective success and positively related to subjective success, openness to experience and internal locus of control are positively related to salary (but not promotions) and subjective success, and cognitive ability is positively related to salary. In general, the personality factors were more strongly related to career satisfaction than to salary or promotions. A variety of other stable individual difference variables (e.g., achievement motivation, self-monitoring, leadership motivation, masculinity, core self-evaluations, self-confidence, optimism, and a strong PCO) have also been associated with one or more indicator of career success in the literature. Ng et al.'s (2005) demographic characteristics included race, sex, age, and marital status, all of which were related to at least one indicator of career success. Because only four characteristics were included in the meta-analysis, it is difficult to draw conclusions regarding the broad impact of demographic factors on career success.

Moderated Relationships

Although a variety of factors are related to career success, the relationships tend to be inconsistent across studies and suggest the potential usefulness of examining moderators of predictor–success relationships. The most compelling evidence is the large percent (73%) of Ng et al.'s (2005) meta-analyzed relationships with significant Q statistics suggesting sufficient variability in effect sizes across studies to consider the plausibility of moderation. This should not be surprising in light of the importance of context in shaping organizational behaviors and outcomes (Johns, 2006).

It is not difficult to find evidence of moderators within each antecedent category. For example, Judge and Hurst (2007) found that educational attainment (a human capital investment) and family advantages (a demographic composite of parents' education and occupational status and freedom from poverty) had positive effects on salary at midlife only for employees with high core self-evaluations. Within the realm of organizational sponsorship, Pan, Sun, and Chow (2011) found that the extent to which personal learning mediated the effects of mentoring on subjective career success depended upon employees' level of self-efficacy. In addition, the impact of personality on career success may depend on the countries in which employees work (Boudreau, Boswell, & Judge, 2001), the types of occupation they pursue (Seibert & Kraimer, 2001), and the weakness or strength of situational cues (Judge & Kammeyer-Mueller, 2007).

One contextual factor that can affect career success is an employee's family responsibilities and experiences. Individuals take family considerations into account in making such work-domain decisions as how much time to commit to work and whether to quit a job (Powell & Greenhaus, 2010) that can ultimately affect the success of their career. That only one family characteristic (marital status) was included in Ng et al.'s (2005) meta-analysis may underestimate a growing literature on the effect of family life on career outcomes. Moreover, because the effects of family and employee sex on career success are closely interconnected, we discuss them together in the following section.

The Meaning of Career Success to Men and Women

The literature suggests that men and women use somewhat different criteria when they gauge the success of their career and also may experience different levels of career success. Moreover, both of these phenomena may be linked to the role of relationships and family in women's and men's lives.

Just as women's relational orientation may lead them to view their career in a more complex, holistic manner than men (Mainiero & Sullivan, 2006), so too might women's view of career success be somewhat different (and perhaps broader) than men's view of success. Several sets of findings lead us in that direction. First, Ng et al.'s (2005) meta-analysis indicated that although women earned less money and received fewer promotions than men, they reported no less subjective career success (career satisfaction), suggesting that women do not base their perception of career success primarily in terms of money and advancement. In support of this notion, Mayrhofer, Meyer, Schiffringer, and Schmidt (2008) found that there was no relationship between objective and subjective career success for women, although there was a positive relationship between these variables for men. Similarly, experiencing an employment gap (which has a negative effect on objective career success) was associated with lower levels of career satisfaction for men but not women (Reitman & Schmeer, 2005). These findings are consistent with the relative importance men place on status-based factors in their career (e.g., salary, rapid promotions) and the importance women place on socioemotional factors such as helping others and working for a company that puts people first (Eddleston, Veiga, & Powell, 2006).

Moreover, whereas men define career success in terms of accomplishments residing within the work domain, it is possible that women view career success in terms of experiencing positive relationships with others (Gallos, 1989)

and achieving balance between career and family (Gerson, 1993; Gordon & Whelan, 1998). Women's careers cannot be separated from the larger context of relationships, including relationships outside the work domain (Mainiero & Sullivan, 2006; Powell & Mainiero, 1992) and as a result, their work identity (and perhaps their meaning of a successful career) extends beyond job-related accomplishments and includes concerns regarding balance, interdependence, and connectedness with others (Mainiero & Sullivan, 2006).

The Achievement of Career Success by Men and Women

The tendency of men to earn more money and receive more promotions than women (Ng et al., 2005) should unfortunately be of no surprise to readers. Despite recent progress that women have experienced in attaining and progressing through managerial and professional positions, the glass ceiling has not disappeared (Lyness, 2006). Understanding the factors that explain sex differences in objective career success has inspired extensive research over the years.

Efforts to control for variables thought to explain sex differences in career success (e.g., human capital, family responsibilities, work investments, socioeconomic background, and organizational characteristics) have met with mixed success. Although some studies show that sex differences in salary, promotions, and/or organizational level disappear when controlling for a variety of work and non-work factors, other studies indicate that sex differences in at least some indicators of objective success persist after controlling for these variables (Chênevert & Tremblay, 2002; Kirchmeyer, 1998, 2006; Stroh, Brett, & Reilly, 1992; Tharenou, Latimer, & Conroy, 1994). It is safe to conclude that we do not have a theoretically grounded understanding of why and under what conditions men experience more objective career success than women.

In addition to examining sex differences in the level of career success, research has explored whether the determinants of career success are similar or different for men and women. The findings have not provided overwhelming support for the notion that different factors predict the career success of men and women. For example, Kirchmeyer (1998) found that employee sex moderated only 8 of 36 predictor-criterion relationships, a percentage quite close to Melamed's (1995) 9 of 46 relationships and Ng et al.'s (2005) 5 of 29 meta-analyzed relationships of human capital and organizational sponsorship variables with objective career success. Although different determinants of career success for men and women have been

observed in some individual studies (Chênevert & Tremblay, 2002; Eddleston, Baldrige, & Veiga, 2004; Forret & Dougherty, 2004), there does not appear to be a consistent pattern that runs through the literature, with perhaps one interesting exception, the family domain.

Recent research on the work–family interface indicates that family role experiences can constrain one’s career. Family responsibilities, especially those involving child-care, can discourage working long hours, restrict extensive travel, and play a role in turning down developmental assignments, all of which can inhibit objective career success. Moreover, it is possible that family responsibilities have a greater negative impact on the career success of women than men. For example, in their qualitative review of relationships between family factors and work-domain decisions, Powell and Greenhaus (2010) concluded that family considerations were more likely to restrict the work hours of women than men. Moreover, women’s family or childrearing responsibilities (but not men’s) are positively related to the selection of a job thought to provide work–family balance (Kirchmeyer, 2006) and are negatively related to work centrality (Mayrhofer et al., 2008) and willingness to relocate (Eddleston et al., 2004). Although exceptions appear in the literature, women’s career success is more likely than men’s to be dampened by their family responsibilities, especially women working for unsupportive employers (Friedman & Greenhaus, 2000).

Of course, family need not be a drag on one’s career. Participation in family and other nonwork roles can provide resources that enrich one’s work life (Greenhaus & Powell, 2006) and enhance one’s career (Graves, Ohlott, & Ruderman, 2007; Ruderman, Ohlott, Panzer, & King, 2002). For example, substantial percentages of the women executives in Ruderman et al.’s (2002) study reported that their experiences in their families and communities improved their interpersonal and multitasking skills, increased their psychological resources, and provided emotional support and advice.

The possibility that nonwork commitments can have both negative and positive effects on work and career is revealed in a recent study of nonmanagerial women (Weer, Greenhaus, & Linnehan, 2010) who found that psychological commitment to nonwork roles simultaneously (a) provided resources that enhanced job performance and (b) drained the women of emotional energy that detracted from their job performance. However, the negative path through emotional energy was stronger than the positive path through resource acquisition, with the resultant negative net effect of nonwork commitments on job

performance. It is plausible that the relative strengths of negative (conflict) and positive (enrichment) effects of nonwork lives on career outcomes are contingent on the sex of the employee, the amount of autonomy on the job, the flexibility of the employer, and the support received at home.

Future Research on Career Success

Research should incorporate a wider array of indicators of success to make them more relevant to the pursuit of contemporary careers. Although the examination of objective and subjective career success represents a step in the right direction, it does not go far enough. The use of these composite measures can mask relationships that might otherwise emerge with more fine-grained assessments of success. It would be particularly useful to develop scales that inquire into an individual’s conception of what it means to be successful in his or her career and then assess objectively defined accomplishments and/or perceived success in each of these areas. Different models of career success—not merely objective success and subjective success—could result from these studies that represent alternative paths to fulfillment in a career.

The models are likely to include somewhat different predictors because the factors that determine advancement, for example, may not be the same as those that determine work–family balance. Although it is trite to recommend that the predictors of success should be based on a theoretical framework, the literature is not particularly strong in that regard (see Judge and Kammeyer-Mueller [2007] for an interesting exception). Although most of the studies include reasonable sets of variables (e.g., human capital, motivational), the theoretical rationales for the specific variables within these sets have not always been persuasive.

The inclusion of a more varied set of career success indicators could also provide information regarding the tendency of individuals to experience career success along more than one dimension. For example, can individuals simultaneously experience success with regard to advancement strivings and their need to establish strong interpersonal relationships? What are the individual and situational factors that distinguish patterns of career success (e.g., high in advancement and low in work–family balance versus high in both)? In short, an expanded conceptualization and measurement of career success should produce research that is relevant to individuals pursuing a wide array of career motives.

MENTORING

Having the support of a mentor has long been regarded as a crucial determinant of career success (Kram, 1983). Mentors are thought to provide two types of assistance—career support (sponsorship, exposure and visibility, coaching, protection, and challenging assignments) and psychosocial support (acceptance and confirmation, counseling, role modeling, and friendship)—to enhance protégés' personal and work-related effectiveness.

Meta-analytic research has confirmed the association between mentoring (having a mentor and receiving career and/or psychosocial support) and a wide variety of career outcomes (Allen et al., 2004) even when controlling for demographic and human capital variables and core self-evaluations (Kammeyer-Mueller & Judge, 2008). At the same time, it is recognized that the benefits of mentoring may be modest when compared to the impact of other facilitators of career success (Kammeyer-Mueller & Judge, 2008) and should be considered as just one of a number of career resources that can promote positive outcomes (Singh, Ragins, & Tharenou, 2009). Moreover, although formal mentoring relationships are generally thought to be less effective than informal mentoring relationships (Ragins & Cotton, 1999), formal programs can promote positive work attitudes if the protégé is satisfied with the mentoring relationship (Ragins, Cotton, & Miller, 2000). Given the popularity of mentoring programs, it is important that research has begun to identify characteristics of formal programs (e.g., input into the selection of a mentor or protégé, quality of mentor training) that can enhance their effectiveness (Allen, Eby, & Lentz, 2006).

One limitation of the early mentoring literature had been the neglect of the processes that mediate the effects of mentoring on more distal outcomes (Wanberg, Welsh, & Hezlett, 2003). This shortcoming has begun to be addressed in recent studies that explore the process by which mentoring is effective, considering such factors as the commitment of the mentor (Allen & Eby, 2008), perceptions of perceived organizational support (Baranik, Roring, & Eby, 2010), personal learning (Pan et al., 2011), and feedback seeking and acceptance (Allen, Shockley, & Poteat, 2010).

Consistent with a relational perspective that views mentoring as an interdependent process of mutual learning and empowerment (Ragins & Verbos, 2007), research has broadened its examination of the benefits of a mentoring relationship to include the mentor. Not only can mentors satisfy their generativity needs through assisting younger employees in their career (Allen, Poteat, & Burroughs,

1997), but they can also experience heightened levels of job performance, career advancement, and social status at work (Allen, Lentz, & Day, 2006; Bozionelos, 2004; Liu, Liu, Kwan, & Mao, 2009) perhaps due to the personal learning and high-quality social interactions associated with providing extensive mentoring (Liu et al., 2009). Serving as a mentor also seems to buffer individuals from some of the negative effects of being stuck in a job that offers few opportunities for further learning and development (Lentz & Allen, 2009).

Although the majority of the research has focused on the potential benefits of mentoring, Scandura (1998) provides a different perspective by exploring the dysfunctional characteristics of mentoring relationships. By focusing on such potentially dysfunctional behaviors as bullying, revenge, and betrayal, Scandura (1998) has applied the psychological literature on abusive relationships to the mentoring process and has broadened the scope of research on the mentoring process. In a similar vein, Eby and colleagues have confirmed five dimensions of negative mentoring and have linked negative mentoring to process (e.g., social exchange perceptions) and outcome (e.g., depressed mood) variables (Eby, Butts, Lockwood, & Simon, 2004). The research on dysfunctional and negative mentoring provides a useful balance within the mentoring literature.

In several respects, mentoring research appears to have been implicitly linked to the conception of a traditional linear organizational career. Much of the research defines a mentor as coming from the same organization as the protégé, in contrast to the external social networks that are thought to sustain individuals pursuing boundaryless careers (Arthur & Rousseau, 1996). In addition, the vast majority of the dependent variables in mentoring research (e.g., job performance, salary, promotion rate, socialization effectiveness, job satisfaction, organizational commitment) are outcomes that seem particularly relevant to a protégé's current employment setting (Arthur et al., 2005) and are generally limited to economic, instrumental benefits (Ragins & Verbos, 2007). Nevertheless, Greenhaus et al. (2008) observed that the mentoring literature has increasingly incorporated elements of nontraditional careers in its theory and research.

For example, the literature has recognized that protégés can establish a range of developmental relationships rather than relying on an exclusive mentoring relationship (Ragins & Verbos, 2007). This perspective has encouraged scholars to consider the reasons why employees may seek mentoring relationships that cross organizational boundaries, including the shortage of managers in their

downsized organization (De Janasz, Sullivan, & Whiting, 2003), technological innovations that permit online mentoring (Ensher, Heun, & Blanchard, 2003), and extensive interorganizational mobility that puts a premium on information and assistance regarding a wide variety of occupations, organizations, and industries (Baugh & Fagenson-Eland, 2005).

Empirical research is too limited at the present time to provide a comprehensive picture of the relative effectiveness of extra- versus intraorganizational mentoring (Baugh & Fagenson-Eland, 2005; Higgins & Thomas, 2001). However, it is clear that future research along this line should define a mentor broadly enough to include an individual who resides outside the organization (Baugh & Fagenson-Eland, 2005) and should permit respondents to identify more than one mentor (inside and/or outside the organization) and assess the mentoring functions, processes, and outcomes associated with each source of support (Higgins & Thomas, 2001). Moreover, the conceptualization and measurement of some of the mentoring functions (e.g., sponsorship, exposure/visibility) may have to be expanded to go beyond the protégé's current employment setting (Greenhaus et al., 2008).

Future Research on Mentoring

Research should continue to examine mentoring within the context of contemporary careers. One way to accomplish that aim is to expand the study of the effects of mentoring on outcomes that can help protégés navigate increasingly unpredictable and nontraditional careers. Such qualities as psychological capital, self-awareness, personal learning, positive emotions, and adaptability can have far-reaching effects on protégés' lives that extend beyond the current job and organization. Some of these qualities, such as personal learning (Liu et al., 2009; Pan et al., 2011), have already been examined as mediators of mentoring on traditional indicators of career success, but they should also be examined as important benefits of mentoring in their own right. So too should work–family balance be examined as a mentoring outcome because of its important relationship to individual well-being (Greenhaus & Allen, 2011). The characteristics of a mentor's schema or construal of the mentoring role (Ragins & Verbos, 2007) are likely to determine whether a mentor tries to help a protégé achieve more balance in life (Greenhaus & Singh, 2007). This takes us full circle to a fundamental question on which there are likely to be strong differences of opinion: Is the purpose of mentoring to help protégés “get ahead” in their current organization or to help them lead authentic, satisfying (work) lives?

CAREER DEVELOPMENT

An overriding theme running through the literature has been the belief that the evolution of an individual's career is characterized by distinct stages that are closely linked to the individual's age. The second half of the 20th century produced a number of age-linked theories of career stages with each career stage associated with somewhat different tasks and challenges. Super's (1957) five stages of career development—growth, exploration, establishment, maintenance, and decline—is representative of this era.

However, during the past several decades, beliefs regarding stage-based patterns of career development have changed dramatically for several reasons. First, age-based models have an implicit assumption that individuals pursue a continuous linear career within one occupation, perhaps one or two organizations, and without major disruptions or redirections, all of which are increasingly unlikely because of the economic, global, and organizational changes discussed earlier in the chapter. Second, it is believed that career stages or cycles in the contemporary work world are shorter in duration and can reoccur over the course of a career as individuals “recycle” back to earlier modes as they change projects, jobs, employers, or occupations. Although chronological age likely still plays a role in understanding the unfolding of a career, an individual can experience lifelong career transitions that result in multiple career cycles as one gets older.

While research on career stages as a total life process has declined, researchers continue to use stages as a way to categorize populations of individuals in an attempt to better understand career-related experiences and outcomes. For example, research regarding the early career focuses on the socialization process as one becomes established within an organization. Although socialization (or establishment) is a stage within most theories of career development, research on socialization has generally been conducted independent of a particular theory of career development. Understanding the socialization process may be particularly important in an era of boundaryless or other nontraditional careers because individuals confront socialization tasks periodically as they move across functional, organizational, and occupational boundaries with increasing frequency.

Research continues to examine the antecedents of successful socialization (Allen, 2006; De Vos, De Clippeleer, & Dewilde, 2009; Gruman, Saks, & Zweig, 2006; Kammeyer-Mueller & Wanberg, 2003; Klein, Fan, & Preacher, 2006). Individual and organizational factors that have been associated with indicators of effective

socialization (e.g., mastery of the job, satisfactory work relationships, understanding the organization's mission, culture, and politics) include the employee's preentry knowledge regarding the job and organization, employee proactivity and self-efficacy, the type and degree of socialization tactics used by the organization, and the communication and interpersonal relationships between the newcomer and established employees in the organization such as supervisors, coworkers, and mentors.

Generational Issues in Career Development

Related to the stage-based view of career development, research on different generations of employees is expanding. While the exact terms used to describe each generation of employees can vary, the most common terms are the *Baby Boom* or those born during the 2 decades after the end of World War II, *Generation X* or those born during the period from the mid-1960s until the end of the 1970s, and *Generation Y* or *Millennials* consisting of those born in the final 20 years of the 20th century.

Much of the research has examined differences between the generations in terms of attitudes toward work and careers (Cennamo & Gardner, 2008; Dries, Pepermans, & De Kerpel, 2008; Hess & Jepsen, 2009; Sullivan, Forret, Carraher, & Mainiero, 2009; Twenge, 2010; Twenge & Campbell, 2008; Westerman & Yamamura, 2007; Wong, Gardiner, Lang, & Coulon, 2008). While some conflicting results have been found (Wong et al., 2008), these intergenerational studies show that the Generation X and Y individuals rate work as less meaningful to their total lives, tend to value leisure time, self-enhancement, and extrinsic work values such as salary more highly, show a greater degree of openness to change, express a lower work ethic, and display more individualistic characteristics than those individuals in the Baby Boom generation (Lyons, Higgins, & Duxbury, 2007; Twenge, 2010).

The bulk of the generational research has studied the older, Baby Boom generation in two distinct ways. At a more micro level, research has examined the attitudes and career experiences of these comparatively older workers (Mignonac, 2008; Ulrich & Brott, 2005), finding, for example, that the availability of appropriate role models is positively associated with organizational commitment and career satisfaction (Gibson & Barron, 2003) and that workers' self-identity (as "older") is associated with a lower level of commitment and a greater willingness to take early retirement (Desmette & Gaillard, 2008). A more macro focus has discussed the organizational, societal,

and governmental implications of the aging of the Baby Boom generation. It is increasingly recognized that the Baby Boom generation presents multiple challenges for organizations because it is a critical resource that requires attention in terms of recruitment, selection, development, engagement, and retention. Moreover, as they age, Baby Boom employees are forcing organizations to make strategic reassessments of such career-related programs as employee health care, pensions, preretirement and retirement systems, and outplacement (Callanan & Greenhaus, 2008; Gandossy & Efron, 2004).

Career Transitions

One area of career development that continues to receive considerable attention is the career transition (Rudisill, Edwards, Hershberger, Jadwin, & McKee, 2010), that is, an event that can occur throughout the life cycle and involves a voluntary or involuntary shift in an individual's career path (Heppner & Scott, 2006). Because another chapter in this volume is devoted to job transitions (Feldman), we only briefly discuss two career transitions that are particularly relevant to contemporary society. With ongoing organizational downsizings and mass labor shifts, it is not surprising that much of the research on career transitions focuses on job loss. This research has addressed such issues as the unemployment experience, outcomes of unemployment, coping with job loss, the impact of unemployment on family members, and the role of employability in the transition to reemployment (Fugate, 2006; Fugate, Kinicki, & Ashforth, 2004; McArdle, Waters, Briscoe, & Hall, 2007; McKee-Ryan, Song, Wanberg, & Kinicki, 2005).

Another career transition that has received attention is the movement of older workers into alternative career paths prior to full retirement either by choice or necessity (Owen & Flynn, 2004). One type of transition, phased retirement, generally refers to situations in which older workers remain with their employer while gradually reducing work hours as a step toward full retirement while continuing to exercise skills developed earlier in their career (Hutchens & Grace-Martin, 2006). In contrast, bridge employment allows workers who have retired from a "career-oriented" job to move to a transitional work position that typically involves fewer hours, less stress, more flexibility, and fewer physical demands, thereby serving as a bridge between one's long-term career and full disengagement from work (Ulrich & Brott, 2005). The combined effects of layoffs, the aging of the Baby Boom generation, and the potential need for an individual to

maintain a higher income level before full retirement will likely make these temporary work options more prevalent and require additional research to understand these transitions from individual and organizational perspectives (Callanan & Greenhaus, 2008).

Career Exploration

Career exploration involves the gathering of information about oneself and the environment as a way to foster awareness, produce effective decisions, and stimulate career growth (Zikic, 2006). Because the turbulent economic environment has produced shorter and more frequent career cycles that require individuals to make a greater number of significant career decisions, career exploration is currently viewed as an activity that occurs throughout the lifespan (Zikic & Hall, 2009). Research has considered the internal and external factors that can initiate career exploration, the approaches used in undertaking the activity, and the outcomes of exploration (Jepsen & Dickson, 2003; Klehe, Zikic, van Vianen, & de Pater, 2011; van Vianen, De Pater, & Preenen, 2009; Zikic, 2006).

The need for career exploration results from various triggers that emanate from within the individual and from external events (Zikic, 2006). Internal factors that trigger career exploration include a highly salient career role as well as such personality characteristics as self-efficacy, proactivity, conscientiousness, and openness to experience (Nauta, 2007; Reed, Bruch, & Haase, 2004; Zikic, 2006). External factors that prompt exploratory behavior include work-related (e.g., an organizational downsizing) and non-work-related (birth of a child) changes that require individuals to gain insight into themselves and/or the world around them (Zikic, 2006; Zikic & Klehe, 2006; Zikic & Richardson, 2007).

Career exploration has been associated with a variety of positive outcomes, including the establishment and accomplishment of career goals, achievement of fit between the person and the work environment, discovery of new career opportunities, adaptability to new work situations, and enhanced self-awareness that improves interpersonal relationships in work and nonwork domains (Klehe et al., 2011; van Vianen et al., 2009; Weng & McElroy, 2010; Zikic, 2006; Zikic & Hall, 2009). In this sense, the immediate consequence of career exploration is not necessarily the arrival at a career decision but rather the preparedness and ability to positively respond to career demands (van Vianen et al., 2009). However, career exploration has also been linked with potential negative or “maladaptive” outcomes. For example, the uncertainty of the job market

might prompt some individuals to engage in frequent or continuous exploration (Boswell, Boudreau, & Dunford, 2004) that may become haphazard and unsystematic, thereby leading them to make unwise career decisions based on incomplete or spurious information (Zikic & Hall, 2009).

Future Research on Career Development

Despite many of the outmoded assumptions of age-related theories of development, it is important not to disregard the effects of age on careers. Individuals change in many ways as they get older, including their work motivations and attitudes (Kanfer & Ackerman, 2004). Although one can cycle back to the previously encountered tasks of organizational entry and socialization when changing projects, jobs, employers, or occupations, one cannot cycle back from late adulthood to middle adulthood to early adulthood. It is therefore important for future research to determine whether the tasks associated with entering and managing a career cycle are handled more or less effectively as one ages.

In addition, while a great deal of research has examined the career decision-making strategies used by high school and college students, surprisingly little research has focused on employees, an important gap in light of the need to make a greater number of career decisions in a boundaryless era. In one of the few studies of employee career decision-making strategies, R. Singh and Greenhaus (2004) found a higher level of person–job fit when employees consider both facts and feelings, by using their “head” (rational) and their “heart” (intuition), in deciding whether to accept a new job. Future research should examine the effectiveness of alternative career decision-making strategies in different contexts and for discrete populations, especially in developing and underdeveloped geographic sectors around the world (Inkson, Khapova & Parker, 2007; Sullivan & Baruch, 2009; Weng & McElroy, 2010; Zikic & Hall, 2009).

THE INTERNATIONALIZATION OF CAREERS

The globalization of business activity, where both large and small companies have commercial interests and relationships that cross to other parts of the world, has reshaped career patterns and influenced individual approaches to career management. An international career is one in which the employee “performs a series of international jobs, including international work, over a long

period of time” (Tharenou, 2006, p. 398) such that the career unfolds “across the boundaries of several countries” (Tams & Arthur, 2007, p. 86).

International careers take several different forms (Tharenou, 2006). First, expatriate career assignments can involve the physical relocation of the individual from the parent company in his or her home (or base) country to a subsidiary operation in a host (or foreign) country, usually for some set period of time (Selmer, 2006). A second form of an international career involves “flexpatriate” work assignments (Mayerhofer, Hartmann, Michelitsch-Riedl, & Kollinger (2004) that periodically require an individual to travel to, and work in, one or more foreign countries. In the third form of international career, an individual in a home or base country is employed by an organization that is headquartered in another country. In this case the individual’s work does not necessarily require international travel but might require adaptation to the foreign organization’s management style, culture, and performance expectations.

All three forms of international careers can have positive and negative consequences for the individual. Not surprisingly, the majority of the research attention has been directed at the career issues surrounding foreign assignments that potentially cause disruptions to the individual’s career and can pose challenges to the work–family relationship. In addition, the literature on international careers has recognized the need for the development of distinct “global” competencies that facilitate the formation of career capital and help ensure career success in the short and long term (Tams & Arthur, 2007).

Career Issues Related to Expatriation and Repatriation

The bulk of the research on international careers has focused on the implications of expatriation for both the individual and the organization. From an individual career perspective, the primary concern over an expatriate assignment is whether it helps facilitate the accomplishment of career goals and contributes to longer-term career success. Research has defined expatriation success as consisting of several outcomes, including adjusting to the foreign assignment and the culture of the host country, fully completing the assignment, performing well in the assignment, and remaining with the parent organization once the assignment is over (Shaffer, Harrison, Gregersen, Black, & Ferzandi, 2006; Stahl & Caligiuri, 2005). Various individual factors have been linked with success criteria in an expatriate assignment, including such characteristics as

the individual’s national origin, race and ethnicity, gender, age, personality, cultural motivation and flexibility, degree of task orientation, and degree of ethnocentrism (Chen, Kirkman, Kim, Farh, & Tangirala, 2010; Shaffer et al., 2006; Stahl & Caligiuri, 2005). Factors associated with a higher degree of cultural and work adjustment (e.g., conscientiousness, extraversion, emotional stability, openness to experience, cross-cultural motivation to succeed, and a lower level of ethnocentrism) are not necessarily the same as factors positively associated with job performance (e.g., age, intelligence, prior work performance, and tenure in the expatriate assignment).

Research has also assessed the influence of organizational, environmental, and contextual factors on expatriate success (Benson & Pattie, 2009; Chen et al., 2010; Kraimer & Wayne, 2004; McCaughey & Bruning, 2005; Olsen & Martins, 2009). Findings indicate that support from the host country subsidiary and from the host country national employees plays a substantial role in facilitating an individual’s adjustment to the expatriate assignment and that the amount of time spent in the host country and low levels of cultural distance between the home and host countries facilitate the employee’s nonwork adjustment during expatriation and strengthen the intention to stay in the assignment. Illustrating the interactive effects of personal and situational factors on expatriate success, Chen et al. (2010) found that the impact of an individual’s cross-cultural motivation to succeed in an expatriate assignment on the expatriate’s adjustment was stronger when the degree of cultural distance was low than when it was high.

There is also an emerging body of research on the influence of expatriation on the individual’s relationship with his or her family (Brown, 2008; Lazarova, Westman, & Shaffer, 2010; Takeuchi, Seokhwa, & Tesluk, 2002). Lazarova et al.’s (2010) comprehensive model of expatriate work and family performance depicts a mediational process by which resources and demands influence performance in the work and family domains through affective, cognitive, and behavioral variables. They also emphasize the importance of both spillover (between work and family) and crossover (between partners) processes at different phases of the model to illustrate how family relationships can produce both positive and negative synergy and thereby positive and negative career outcomes related to the expatriate assignment.

In terms of the repatriation process, research has primarily concentrated on the career implications of the readjustment of the expatriate and his or her family when brought back to the parent company and the home country

(Andreason & Kinner, 2005; Hyder & Lövblad, 2007; Osman-Gani & Hyder, 2008; Shen & Hall, 2009). The repatriation process has clear career implications because of the importance of the employee's successful reassimilation into the culture and work processes back home (MacDonald & Arthur, 2005). In addition, depending on the nature of the expatriate assignment, the parent company and the individual can use the knowledge and the skills gained through the assignment to improve individual functioning and organizational performance (Fink, Meierwert, & Rohr, 2005).

A number of factors have been assessed for their influence on the success of repatriation, including the plans and preparation for the employee's return home, the potential for "reverse" culture shock once the employee and his or her family return home, the degree of challenge in the work position, and the ease or difficulty faced by the employee's family in becoming reestablished in the home country (Osman-Gani & Hyder, 2008). In addition, the literature identifies a number of strategies to reduce the degree of uncertainty faced by the returning employee and his or her family (MacDonald & Arthur, 2005) and facilitate a successful repatriation process, such as the development of proactive plans for the repatriation with sufficient dialogue on the timing and logistics of the transfer (Wittig-Berman & Beutell, 2009) and discussions surrounding the potential career plans and paths the employee could reasonably follow (Baruch, Steele, & Quantrill, 2002; MacDonald & Arthur, 2005).

International Careers and the Building of Career Capital and Competencies

A substantial amount of attention has been paid to the manner in which international career assignments can build individuals' career capital and competencies (Dickmann & Doherty, 2010; Haslberger & Brewster, 2009; Mäkelä & Suutari, 2009), including the development of their knowing-why, knowing-how, and knowing-whom competencies (Suutari & Mäkelä, 2007). Although research on the linkages between international career activities and the building of distinct competencies is mostly anecdotal or qualitative, the evidence does suggest that these activities can potentially lead to an expanded skill set, a better understanding of the culture and work contexts in other parts of the world, and the building of global social networks (Kohonen, 2005; Suutari & Mäkelä, 2007). Indeed, multinational corporations see the development of these individual capabilities as a way to develop managers and leaders to be successful in multiple global contexts (Yan, Zhu, & Hall, 2002).

Future Research on International Careers

There are several areas where further research on international careers would be useful. First, with regard to expatriate assignments, research should continue to assess differences in background factors, experiences, and outcomes for assigned versus self-initiated expatriates and examine the decision to repatriate, especially when that decision is being made by "in-demand" self-initiated expatriates who might otherwise be expected to remain working within the host country (Tharenou & Caulfield, 2010). Second, because most of the research on international careers has examined expatriation and repatriation, future studies should explore the other two forms of international careers (Tharenou, 2006), involving periodic travel to foreign operations and employment by a parent organization headquartered in a foreign country.

Moreover, future research should continue to investigate the efficacy of career planning, education, and training that prepare individuals for international business careers. Because there is a growing international interest in these matters (Savickas, Van Esbroeck, & Herr, 2005), further evaluation is needed on how, when, and where different career theories and techniques can be applied successfully in various global contexts (Hartung, 2005; Van Esbroeck, Herr, & Savickas 2005). In addition, research should assess the degree to which educational and training programs in international business actually lead to improvements in the capabilities and successes of international business leaders. Although university coursework and management development programs continue to place greater emphasis on international business practices and an understanding of foreign cultures, additional research is required to assess the impact of these learning programs on the development and advancement of individuals involved in international careers.

ENTREPRENEURIAL CAREERS

Interest in entrepreneurial careers continues to grow, reflecting the important role that entrepreneurs play in the economic well-being and overall welfare of societies around the world, spurring economic growth, creating jobs, anchoring communities, and serving as role models for future generations of business owners (DeCarolis & Litzky, 2006; van Praag & Versloot, 2007). An entrepreneurial career is different from a traditional organizational career in that it involves a substantially higher degree of personal commitment and a willingness to take on a higher

level of risk involving personal, financial, and career failure (Greenhaus et al., 2010). Because of its economic and social importance, entrepreneurship generates substantial interest from both policymakers and academics focused on the factors that spark entrepreneurial pursuits and sustain the commitment to entrepreneurial careers (DeCarolis & Litzky, 2006).

Research on entrepreneurial careers continues to evolve and reflects several different perspectives. Numerous studies over the past three decades have assessed whether entrepreneurs possess, at least in contrast with the general population, certain personality and psychological characteristics, traits, and attitudes that predispose them to the undertaking of, and success in, entrepreneurial ventures. In addition, research has examined the environmental and situational factors and opportunities that might draw individuals into entrepreneurial careers. While most of this research focuses on entrepreneurs in the United States, more recent research has examined whether these factors are meaningful in the prediction of entrepreneurship in other parts of the world. Another stream of research examines sex differences in entrepreneurial careers, primarily focused on the question of whether women entrepreneurs possess the typical entrepreneurial profile and display similar background and learning experiences as those of men. In a similar fashion, a number of studies have explored differences in personality, background factors, and career experiences of minority and nonminority entrepreneurs. We discuss each of these perspectives below.

Individual Characteristics and Entrepreneurial Careers

Linkages of personality and other individual characteristics with entrepreneurial careers have been studied extensively (Zhao, Seibert, & Lumpkin, 2010). Despite the presence of somewhat inconsistent findings, there is evidence to suggest that many individual characteristics have a discernible influence on the undertaking and success of an entrepreneurial career (Greenhaus et al., 2010).

The personality variable that is perhaps most often associated with entrepreneurship is a preference for autonomy and independence because of the presumption that the pursuit of an entrepreneurial career is one of the primary ways that individuals can find an outlet for these needs. Research shows that the need for freedom, the lack of patience with formal corporate structure, and a high degree of cynicism toward the meaningfulness of corporate work can drive people out of corporations and into their own business (Douglas & Shepherd, 2002).

Risk-taking propensity is another common element in describing the entrepreneur (Miner & Raju, 2004; Stewart & Roth, 2001; Zhao et al., 2010). As with other personality variables, research has shown some degree of inconsistency and disagreement regarding the strength of risk-taking propensity as a personality trait of entrepreneurs (Miner & Raju, 2004), although recent studies have indicated that entrepreneurs can be differentiated with respect to tolerance and propensity for risk taking (Douglas & Shepherd, 2002; Stewart & Roth, 2001; Zhao et al., 2010).

Moreover, although high achievement motivation is characteristic of many successful managers, entrepreneurs seem to be moderately higher in achievement motivation than organizational managers (Stewart & Roth, 2007) and meta-analytic (Collins, Hanges, & Locke, 2004) and cross-cultural (de Pellis & Reardon, 2007) research indicates that achievement motivation is positively related to the choice of an entrepreneurial career as well as entrepreneurial performance. Research also shows associations of entrepreneurial entry and/or success with an internal locus of control (Hansemark, 2003), entrepreneurial self-efficacy (Baum & Locke, 2004; Zhao, Seibert, & Hills, 2005), positive dispositional affect (Baron, 2008), and a tolerance for ambiguity (de Pellis & Reardon, 2007).

Attention has also been directed at the role that job dissatisfaction plays in the pursuit of an entrepreneurial career. This research has shown that dissatisfaction with one's current job is a form of "negative displacement" that can serve as a primary reason for individuals to embark on an entrepreneurial career (Greenhaus et al., 2010). In addition, not only can dissatisfaction push aspiring entrepreneurs from their previous place of employment, but the expectation of greater job and life satisfaction can pull individuals into an entrepreneurial career (Schjoedt & Shaver, 2007).

Situational Factors and Entrepreneurial Careers

Beyond the individual factors associated with entrepreneurship, another stream of research focuses on situational variables that influence the undertaking of an entrepreneurial career. These factors include entrepreneurial role models, economic or societal encouragement, availability of training and educational programs, and the experience (or threat) of job loss.

Research affirms the positive effect of role models not only on intentions to embark on an entrepreneurial career (Van Auken, Fry, & Stephens, 2006) but also the degree of persistence once the venture has been started (Burke,

FitzRoy, & Nolan, 2008). For example, parents can play an influential role encouraging their children to pursue entrepreneurial careers, including parents who are themselves involved in an entrepreneurial career (de Bruin & Lewis, 2004; White, Thornhill, & Hampson, 2007). While positive feedback and encouragement can improve the expectancies of aspiring entrepreneurs regarding prospects for entering an entrepreneurial career (Gatewood, Shaver, Powers, & Gartner, 2002), once an entrepreneur becomes well established, the importance of role models and the feedback they provide can diminish considerably. Moreover, given the importance of risk taking and decisive action in entrepreneurial careers, advice from role models might delay or inhibit the entrepreneur from acting in a required fashion (Greenhaus et al., 2010).

Economic and societal support for entrepreneurial careers can take many forms. The literature recognizes the value of social networks as instrumental in the undertaking of, and progress in, an entrepreneurial career (DeCarolis & Litzky, 2006; DeCarolis & Saporito, 2006; Terjesen, 2005). In addition, economic networks can facilitate entrepreneurial careers by providing the entrepreneur with efficient access to resources and information that otherwise would not be available (Hanson & Blake, 2009; Witt, 2004). Training courses and educational degree programs at the university level, now numbering in the thousands, are designed to meet the needs of students interested in an entrepreneurial career (Fayolle, 2008; Kuratko, 2005). These programs can play an important role in the career exploration process by providing individuals with self-insight regarding whether an entrepreneurial career represents a fit with their personality and background (von Graevenitz, Dietmar, & Weber, 2010) and by enhancing individuals' entrepreneurial self-efficacy (Wilson, Kickul, Marlino, Barbosa, & Griffiths, 2009). Thus, while some question whether entrepreneurship can be taught (Neck & Greene, 2011; Politis, 2005), coursework and degree programs do seem to serve a useful purpose.

Widespread job loss associated with corporate downsizings as well as continuing high unemployment and underemployment are additional factors that can influence the undertaking of an entrepreneurial career (Bosma, de Wit, & Carree, 2005; Carree, van Stel, Thurik, & Wennekers, 2002). Moreover, individuals taking early retirement, either by choice or necessity, represent a growing segment of nascent entrepreneurs (Singh & DeNoble, 2003), many of whom view starting (or acquiring) their own business as a viable career choice, especially when there are limited options for remaining in a traditional organizational career.

The Entrepreneurial Careers of Women and Minorities

Over the past 2 decades a substantial amount of research has studied the career experiences of women entrepreneurs (Ahl, 2006; de Bruin, Brush, & Welter, 2006, 2007). Much of this research has examined whether women entrepreneurs are different from either their male counterparts or women managers in organizations, and whether there are factors that discourage women from entering or excelling in entrepreneurial careers. Research into the career experiences of minority entrepreneurs, while less extensive, tends to follow the same paths as that for women entrepreneurs.

With regard to the first question, earlier research had generally found few differences between women entrepreneurs and either men in entrepreneurial careers or organizational managers in terms of the individual characteristics typically associated with entrepreneurship, including the need for achievement, desire for autonomy, risk-taking propensity, level of education, prior work experience, and the degree of planning conducted (Malach-Pines & Schwartz, 2008). More recent research comparing the entrepreneurial self-efficacy of women and men has produced mixed results. Whereas studies of MBA students (Mueller & Dato-On, 2008; Zhao et al., 2005) found no sex difference in entrepreneurial self-efficacy, a study using a broader sample of students and young working adults found that women had lower entrepreneurial self-efficacy than men (Wilson et al., 2009).

With regard to the second question, while women have been entering entrepreneurial careers in record numbers around the world (de Bruin et al., 2006), researchers have found both a lower entrepreneurial career preference among women and a comparatively lower level of actual entry into an entrepreneurial career (Gupta, Turban, Wasti, & Sikdar, 2009; Wilson et al., 2009; Zhao et al., 2005). Reasons invoked to explain these differences include cultural conditioning, a lack of encouragement and role models, and lower self-efficacy expectations (Greenhaus et al., 2010; Langowitz & Minniti, 2007). Gender identity may also play a role in entrepreneurial careers. Gupta, Turban, and Bhawe (2008) found that entrepreneurs were perceived to have masculine traits and individuals who perceived themselves as possessing a strong masculine gender identity showed higher entrepreneurial intentions than those with a weak masculine identity.

Women entrepreneurs have also noted difficulties in such areas as access to credit and economic and social networks (de Bruin et al., 2007) and issues over work and

family roles (Jennings & McDougald, 2007; Shelton, 2006). Several recommendations have been offered to overcome these limiting factors, including increased training and education in entrepreneurship as a way to improve self-efficacy and entrepreneurial intentions, greater access to, and usage of, social and economic networks, and partnering with other women and men to help get new ventures off the ground (Godwin, Stevens, & Brenner, 2006; Hanson & Blake, 2009).

Research on the entrepreneurial experiences of minority group members has produced somewhat similar findings as the research on women. As with women entrepreneurs, there do not appear to be major differences in personal characteristics or individual background factors between minority and non-minority entrepreneurs (Cardon, Shinnar, Eisenman, & Rogoff, 2008). Moreover, research has identified environmental barriers that can either negatively affect minorities' ability to enter an entrepreneurial career or limit advancement of their business and career (Shelton, 2010). Consistent with women entrepreneurs, these barriers include access to credit, more limited opportunities to access social and economic networks, and discrimination (Park & Coleman, 2009).

Future Research on Entrepreneurial Careers

While research into all aspects of entrepreneurial careers has expanded significantly in recent years, there are several areas that require further study. First, despite extensive research, we need to achieve a fuller understanding of the individual characteristics that are most predictive of entry and success in an entrepreneurial career. The inconsistent findings across studies suggest the presence of personal and/or situational moderators that would shed light on the dynamics behind the selection of, and effectiveness in, entrepreneurial careers. Given the social and economic benefits of entrepreneurship in all parts of the world, a better understanding of these individual factors could help counselors assist individuals with their career decision making and policymakers increase the degree of entrepreneurial activity.

Second, research should continue to focus on the influences that social and economic networks have on entrepreneurial careers. Although research has progressed in this area (DeCarolis & Saporito, 2006; Hanson & Blake, 2009; Terjesen, 2005; Witt, 2004), further work is needed regarding the role that social and economic contacts play in entrepreneurs gaining access to advice, mentoring, and financial support. In this regard, specific attention should be given to the role that access to these networks

plays in the development and success of women- and minority-owned entrepreneurial ventures, which can serve as a critical success factor for nascent and established entrepreneurs (Cochrane, 2010; DeCarolis & Litzky, 2006).

Third, future research should continue to examine the implications of entrepreneurial careers for the work–family interface (Shelton, 2006). Entrepreneurial careers, by their nature, often involve an interconnection between the business and the entrepreneur's family (Jennings & McDougald, 2007). Areas for future study include an assessment of sex differences in the achievement of work–family balance, a more fine-grained understanding of the coping strategies used by entrepreneurs in dealing with competing work and family demands, and an examination of the outcomes, both economic and non-economic, of work–family balance issues for entrepreneurs (Jennings & McDougald, 2007; Kim & Ling, 2001). In a related area, future research should continue to look at the experiences and outcomes of entrepreneurial couples where both partners are jointly involved in the business venture. Termed *copreneurship* by de Bruin (2006), research into this rapidly growing form of family business is at an early stage.

CONCLUSIONS

Research has provided considerable insight into career processes since the first edition of this *Handbook* was published in 2003. In a number of respects, the literature has incorporated the contemporary economic and social landscape into its theory and research, especially with regard to the meaning and enactment of a successful career, mentoring, the globalization of careers, and the entrepreneurial process. Moreover, the interdependency between family and work (often in the context of gender-related issues) has been increasingly recognized in scholarship on career success, international careers, and entrepreneurship and represents a perspective that can be profitably incorporated into the examination of career cycles and the mentoring process. Research over the past decade provides a solid foundation for continued study of career dynamics in the years ahead.

Healthy Workplaces

STEVE M. JEX, NAOMI SWANSON, AND PAULA GRUBB

HEALTHY WORKPLACES 615

HEALTHY WORKPLACES

Introduction

Given the amount of time most people spend at work, a major determinant of the overall health of most adults is the extent to which the organizations in which they work facilitate or detract from their health and well-being. Because of this, occupational health and safety of employees has been a major concern of organizations, labor unions, and government agencies for decades. Research in occupational health and safety has also been conducted for decades, largely by those trained in public health, safety engineering, and occupational medicine. It is only recently that psychologists have become interested in occupational safety and health and much of this interest has coincided with the development of the field of occupational health psychology (Barling & Griffiths, 2003, 2011). Thus, one thing we want to make clear is that psychology has been a relatively “late entry” into the field of occupational health and safety.

Despite having not been involved for a long period of time, psychologists have made some very noteworthy contributions to both science and practice within the occupational health and safety arena, and these contributions have improved the health and safety of employees. While we suspect that this is partially due to the ingenuity and drive of psychologists, it also has to do with the fact that many of the variables that impact employee health and safety are psychological in nature. For example, an engineer can design a highly effective piece of safety equipment for construction workers, but if using this equipment slows down progress toward completing a building project, it may never be used. Similarly, if management of an organization promotes the notion of a “healthy workplace,” yet

REFERENCES 637

looks the other way when a supervisor is abusive to his or her subordinates, the goal of achieving a healthy workplace will likely never be achieved.

What the two examples above also illustrate is that occupational health and safety is not the sole province of any one academic discipline, but rather a complex multidisciplinary arena. Keeping this in mind, the purpose of the present chapter is to summarize the current *psychologically based* research that has contributed to the goal of promoting healthy and safe workplaces. The decision to focus on only psychologically based research was made largely because this volume is aimed primarily at psychologists and others in closely related fields (e.g., public health, organizational behavior, and ergonomics). Another more practical reason, however, is that a comprehensive review that delves into all the disciplines that impact employee health and safety would be well beyond the scope of this volume (and most likely beyond the expertise of the authors as well!).

The chapter begins with a brief definition of the terms “health” and “safety”; this is important because these have been conceptualized and measured in different ways. We then shift the focus of the chapter to external forces that have shaped the study of occupational health and safety in the psychological literature. These include legislation that has created regulatory agencies and facilitated research, and more recently the development of the field of occupational health psychology (OHP). After covering these preliminary topics we will then forge into the major topics in the chapter, which will include: (a) conditions within organizations that psychologists have shown to *adversely* impact employee health; we do this largely because most of the research that has contributed to healthy workplaces has examined variables

that adversely impact health; (b) employee safety; (c) “at-risk” groups or those groups of employees who stand a greater chance of being impacted by conditions that negatively impact health and safety; and (d) interventions that are designed to improve employee health. The chapter will conclude with a number of suggestions for future research.

Defining Health and Safety

As a first step in covering healthy workplaces, we must define specifically what we mean by *health*. On first glance, the term *health* would appear to be relatively easy to define. For example, one might argue that health is equivalent to the *absence of pathology or disease* at any particular moment in time. Thus, if one goes to his or her doctor for an annual checkup and nothing unusual is found, then such a person can be considered “healthy.” Unfortunately, declaring such a person as being healthy is a bit premature for a number of reasons. First, a medical checkup designed to reveal physical pathology typically does not take into account one’s overall lifestyle and behaviors that contribute to health. Thus, even though a person may have an absence of physical disease at a particular moment in time, such a person may be engaging in behaviors that are unhealthy. For example, many people who have no physical pathology do not engage in regular physical exercise or may have jobs that require repetitive motions; both of these conditions could lead to health problems in the future even though there may be no evidence of physical pathology at the moment.

The other aspect of health that is often missing when one’s health is assessed by a physician is *psychological* or *emotional* health (Nutbeam, 1998). It is possible that even though a person may have no immediate physical pathology, such a person may not be functioning very well in a psychological or emotional sense. Many studies of occupational stress, for example, use measures of psychological strains such as anxiety, depression, frustration, and emotional exhaustion (see Jex & Britt, 2008, for a summary) to indicate poor psychological or emotional health. Thus, a person who is “healthy” is not only free of physical pathology but is also functioning well in a psychological or emotional sense.

Another point to keep in mind about the concept of health is that it is not confined to individual employees: That is, we can also speak of the “health” of an organization. Although organizations do not experience physical or psychological pathology, it is still possible and in fact useful to talk about the “health” of an organization

as a whole (Wilson, DeJoy, Vandenberg, Richardson, & McGrath, 2004). That is, an organization is healthy to the extent that it is not only financially profitable, but also has employees that are physically healthy and psychologically fulfilled by their work (Quick, 1999). Some readers might argue that these goals are fundamentally incompatible, and we recognize that cogent arguments can be made for this position. We believe, however, that although these goals are not always *easy* to align, it is possible and in fact desirable to do so.

In addition to defining *health*, we must also define what is meant by “safety” because a key aspect of healthy work is that employees are also safe from major work-related hazards. Like the concept of health, *safety* appears relatively easy to define. That is, a safe individual is one who has a low level of accident involvement; similarly, a safe organization is one in which employees collectively have a low level of accident involvement and few lost days from work. While a low level of accident involvement is obviously a goal of most individuals and organizations, this only partially defines the concept of safety. That is, safety also represents the degree to which an organization and its employees insist on safe work practices, and perhaps most importantly, the degree to which those practices are followed regardless of situational pressures (e.g., Humphrey, Moon, Conlon, & Hofmann, 2004). In essence, safety is both an outcome and a part of the cultural fabric of an organization.

In summary, then, we define health and safety in a holistic sense. That is, we can speak of individual employee health in terms of their physical condition, psychological or emotional states, and health-related behaviors they engage in. To determine whether a person is “healthy” we must take into account all three aspects of health. We can also look at health at both individual and organizational levels. Healthy organizations are those that are able to accomplish their primary goals, and do so in a way that does not “burn up” their employees. Stated differently, a healthy organization is one in which a fundamental cultural value is that organizational goals and employee well-being are compatible.

Safety represents more than simply a lack of accident involvement, both at the individual and organizational levels. Rather, it also represents the degree to which employees engage in safe work practices, and organizations insist that they do so regardless of external pressures. It also represents the extent to which employees are looking for ways to make the work environment safer than it currently is, and the extent to which this is part of the culture of an organization.

Occupational Health and Safety Legislation

In the United States, the Occupational Safety and Health Act (OSHAct) of 1970 (Public Law 91-256) established occupational safety and health as an area subject to federal regulation. Language from the OSHAct states that this was legislation

To assure safe and healthful working conditions for working men and women; by authorizing enforcement of the standards developed under the Act; by assisting and encouraging the States in their efforts to assure safe and healthful working conditions; by providing for research, information, education, and training in the field of occupational safety and health; and for other purposes.

The OSHAct established two federal agencies in two separate governmental departments. The Occupational Safety and Health Administration (OSHA) was established in the Department of Labor, and serves a regulatory and enforcement function. The National Institute for Occupational Safety and Health (NIOSH) was established in the Department of Health and Human Services, and serves research and professional training functions. The placement of OSHA and NIOSH in different departments was done to allow occupational safety and health research to be conducted independently of regulatory and enforcement processes. Of primary importance to psychologists interested in occupational health and safety is language in Section 20 of the OSHAct that mandates research by NIOSH relating to occupational safety and health, including “studies of psychological factors involved,” “stresses,” and “research into the motivational and behavioral factors relating to the field of occupational safety and health.” Consequently, NIOSH funding has been instrumental in funding seminal research in the areas of job stress and in the development of the field of occupational health psychology in the United States (L. R. Murphy, 2002).

Occupational Health Psychology: A New Framework for Psychologists

It is increasingly the case that the occupational health and safety community in the United States is confronted with hazards that require expertise in behavioral science (i.e., job stressors, work organization factors). The discipline of psychology has much to contribute to occupational safety and health, and there is a need for psychologists with training in how to reduce workplace exposures to risk factors for injury or illness through work organization interventions (Sauter & Hurrell, 1999). Thus, the

discipline of occupational health psychology was born to form a nexus between psychology and occupational safety and health. OHP concerns the application of psychology to improving the quality of work life, and to protecting and promoting the safety, health, and well-being of workers (L. R. Murphy, 2002). OHP has its roots in business, industrial engineering, sociological, and psychological theories and research from the early 1900s through the 1980s (see Barling and Griffiths (2003), and Sauter and Hurrell (1999) for a history of influences on OHP). In the United States, the discipline was formalized in 1992 when NIOSH entered into a cooperative agreement with the American Psychological Association (APA) to establish post-doctoral training programs in OHP. The training focused on individuals with industrial/organizational psychology backgrounds, with the goal of quickly addressing gaps in competencies needed to address issues related to work organization and worker health and safety. In 1997, the NIOSH/APA collaboration was expanded to foster the development of graduate-level training programs in OHP across the United States. By 2002, when the cooperative agreement ended, there were OHP programs in 11 U.S. universities, many of which continue today as graduate programs. Support for the new discipline also came from the Work, Stress, and Health conference series, begun by NIOSH and APA in 1990, from the *Journal of Occupational Health Psychology*, begun in 1996, and by the establishment of the Society for Occupational Health Psychology (SOHP) in 2005.

While there is no standard “textbook” definition of OHP, we believe that a reasonable way to characterize the field would be: *a multidisciplinary field that utilizes the theories and methods of psychology in order to better understand and enhance employee health and safety.* Two key aspects of this definition should be pointed out. First, although the field of OHP has been developed by psychologists, other disciplines have made major contributions. These include, but are certainly not limited to, public health, occupational medicine, ergonomics, industrial hygiene, and safety engineering. The idea is that psychologists working in collaboration with these other professions can have a bigger impact on occupational health and safety than they would by working in isolation.

The other key aspect of this definition is that the goals of OHP are to *both* understand and enhance the health, safety, and overall well-being of employees. This clearly suggests a dynamic interplay between research and practice, but it is more than that. Drawing largely from a public health perspective, the emphasis in OHP is one of *primary prevention*. More specifically, the goal of OHP is

to identify conditions in the work environment that may adversely impact employees and take steps to prevent those conditions from occurring. Obviously this may not always be possible to do, particularly with some hazardous occupations (e.g., police work, firefighting, military service), but one of the core beliefs of the field of OHP is that most work does not have to be unhealthy or hazardous.

Working Conditions That Impact Employee Health

In any given workplace, employees are exposed to an almost inordinate number of stimuli. Many of these stimuli are physical in nature (e.g., noise level, the design of equipment, the pace of work required), but many others are psychosocial in nature (e.g., relations with coworkers, communication of job requirements). It is our contention that regardless of the job one holds, both physical and psychosocial working conditions impact employees. On balance, though, the relative impact of each of these types of working conditions on employee health and safety likely differs as a function of job type. For example, physical working conditions are probably going to have a stronger effect on the health and safety of blue-collar employees compared to managerial employees.

In contrast, psychosocial working conditions are probably going to have a stronger impact on managerial employees compared to physical working conditions. It is also true, however, that even managerial employees could be impacted by physical working conditions such as high noise levels and blue-collar employees could be impacted by psychosocial working conditions such as poor communication of job requirements. Thus, in recognition of this fact, we cover both physical and psychosocial working conditions that may impact employee health.

Ergonomic Design

Ergonomics refers to adapting work conditions to the physical, cognitive, and psychological capabilities of workers in order to increase their health and well-being (Grandjean, 1980). Ergonomics is an interdisciplinary field, incorporating aspects of physiology, psychology, anthropology, and engineering. Ergonomists have very broad training in work physiology, perception, cognition, skill acquisition, the design of “man–machine systems,” equipment and workplaces, the measurement and design of the physical environment (e.g., lighting, noise, vibration, indoor climate), task analysis, and work organization (e.g., work hours, shift work, work–rest cycles, motivation). Of interest to psychologists is the role that work organization factors, psychosocial factors, and job stressors can play, both

as risk factors interacting with physical environment or job design deficiencies and as factors integral to the success of ergonomic interventions. The following example relates to the investigation of upper-extremity musculoskeletal problems in the office environment.

Musculoskeletal symptoms in office workers are commonplace. For example, a NIOSH study of computer users found that 40% to 44% of the workers reported neck and back discomfort, around a quarter of the workers reported discomfort in their shoulders and right arm, and nearly a third reported discomfort in their right hands (Swanson et al., 2004). There are a wide range of workstation and physical environmental factors that have been linked with musculoskeletal problems in office workers (Hunting, Laubli, & Grandjean, 1981; Ong, Hoong, & Phoon, 1981; Sauter, Schleifer, & Knutson, 1991). These include workstation surfaces that are too high, poor placement of equipment causing poor working postures, and static loads from sitting in the same position for long periods of time. (See the OSHA Web site www.osha.gov/SLTC/etools/computerworkstations/index.html for ergonomic advice on how to configure your computer workstation, work environment, and work tasks.) More recently, psychosocial factors (job content, organizational aspects of the job, interpersonal relationships, temporal aspects of the job) have been noted as potentially playing a role in the etiology of musculoskeletal problems in office workers (Swanson & Sauter, 1999). Two major pathways have been proposed by which psychosocial factors may influence musculoskeletal problems (Bongers, De Winter, Kompier, & Hildebrandt, 1993; Sauter & Swanson, 1996; Smith & Carayon, 1996). In the first pathway, the psychosocial factors may cause physiological strain through a generalized stress response. Early studies indicate that exposure to stressors results in physiological changes such as increases in blood pressure, corticosteroids, and muscle tension, all of which prepare an organism to respond to a threat (Cannon, 1935; Selye, 1946). Work-related stressors, such as boring and repetitive tasks, and low levels of job control, can create similar physiological strains (Frankenhaeuser & Johansson, 1986; Lundberg et al., 1993). Increased muscle tension (Westgaard and Bjorkland, 1987; Lundberg & Melen, 1995) or increases in fluid retention in peripheral body parts (Smith & Carayon, 1996) as a result of these physiological reactions to job stressors have been hypothesized to result in musculoskeletal symptoms (e.g., nerve compression in the carpal tunnel due to fluid retention or sustained low-level elevations in muscle tension induced by the psychological demands of the job).

The second pathway postulates interactive effects between psychosocial and physical factors in which the psychosocial stressors change the physical demands of the job. For example, low levels of job control, high production standards, time pressures, and rigid work procedures can translate into increases in workload, work pace, repetitiveness, work postures, and time on the computer (Smith, Cohen, Stammerjohn, & Happ, 1981). These increases in physical job demands have, in turn, been found to be related to musculoskeletal symptoms (Lim & Carayon, 1995).

As the example above illustrates, psychologists who are trained in the measurement of work organization stressors and in job design can bring much to the design and analysis of ergonomic studies—both etiological and interventional.

Shiftwork

Our 24/7 economy requires many workers to work nonstandard work schedules (evenings, nights, variable hours, and weekends) as well as workdays that extend beyond 8 hours (Presser, 2004). Shiftwork (evening or night schedules) occurs for a number of reasons (Rosa & Colligan, 1997). Critical services, such as police and fire protection, health care, and utilities, are needed 24 hours per day. Some manufacturing or industrial processes have production cycles that are longer than 8 hours and need to run around the clock. Many transportation workers transport items at night to meet morning or “just in time” delivery requirements. Altogether, about two fifths of U.S. workers are in nonstandard schedules, with men and minorities more likely to work these schedules. About one fourth of dual-earner couples have at least one spouse working evening, night, or rotating shifts. If the couple have children, they are even more likely to have at least one spouse working nonstandard hours (Presser, 2004).

Shiftwork and nonstandard work hours are associated with a number of behavioral, social, health, and safety outcomes (Caruso, Hitchcock, Dick, Russo, & Schmit, 2004; Folkard and Lombardi, 2004; Rosa & Colligan, 1997). The body’s circadian rhythm naturally prompts the body to be awake during daytime hours and to sleep during the night. Shiftwork runs counter to natural circadian rhythms, meaning that night workers often feel sleepy or fatigued during their shifts. Shiftworkers must sleep during the daytime when their body clocks prompt them to be awake. Thus, their sleep may be light or disturbed, and their sleep is often two or three hours shorter than that obtained during the nighttime (Rosa & Colligan, 1997). Additionally, shiftworkers may experience stress from having to miss

many family and social functions because they occur during the day when they are sleeping, or during the evening when they are at work. Fatigue and sleepiness experienced during evening, night, and extended work shifts has negative effects on concentration and attention, making it more likely that workers will make errors that can lead to accidents or injuries. This is supported by studies that indicate that accidents and injuries are up to 28% more likely to occur on extended work shifts (10–12 hours), and 30% more likely on night than day shifts (Folkard & Lombardi, 2004). Shiftwork and long work hours are also associated with digestive problems (as regular eating and digestive patterns are disturbed by changing work and sleep times), with cardiovascular disease, and with weight gain (Caruso et al., 2004). There are a number of work schedule design and coping strategies that can help workers to adjust to nonstandard work schedules (Rosa & Colligan, 1997). For example, organizations can avoid schedules that overly disrupt circadian rhythms, such as permanent night shifts, rapid (same-day) shift changes, or more than 2 to 4 consecutive night or extended-hour shifts in a row. They can allow for some weekends off in order for workers to have time with family and friends. Workers can more easily plan their lives if their schedules are regular and predictable. More frequent rest breaks during the work shift can help workers recover from fatigue, or organizations can schedule more demanding work at times when workers are most alert (afternoon and early evening hours). Coping strategies include good sleep hygiene (maintaining a regular sleep routine, blocking out noise and light while sleeping; avoiding heavy foods and alcohol before sleeping), keeping physically fit, maintaining a healthy diet, and avoiding overuse of caffeine, stimulants, or sleeping pills (Rosa & Colligan, 1997).

Job Insecurity/Threat of Layoffs

Beginning with the flurry of mergers and acquisitions in the 1980s (Schweiger & DeNisi, 1991) and continuing to the economic downturn in recent years, many organizations have been forced to reduce the number of employees (Bureau of Labor Statistics, 2011). While a great deal of research over the years has shown the consequences of losing one’s job to be negative (e.g., Cobb, 1974; Leana & Feldman, 1992), it is only in recent years that researchers have begun to pay close attention to the broader psychological fallout from layoffs: namely, the feeling of job insecurity among those who remain on the job.

According to Sverke, Hellgren, and Naswall (2002), job insecurity is defined as the subjective perception of employees that they will experience involuntary job loss

at some time in the future. It is worth noting that most of the research on job insecurity is based on the assumption that such perceptions are based on employees' fear of being laid off due to poor organizational performance, or the broader economic environment. It is also possible that feelings of job insecurity could be due to other reasons (e.g., poor employee performance, skill obsolescence, etc.).

As stated above, empirical research on job insecurity is relatively recent; however, enough research has accumulated to allow for two relatively comprehensive meta-analyses on the topic (e.g., Cheng & Chan, 2008; Sverke et al., 2002). In both of these meta-analyses the strongest negative correlate of job insecurity was trust in one's organization. Job insecurity is also negatively associated with self-reported indices of both mental and physical health, as well as a number of negative attitudinal outcomes (e.g., reduced job satisfaction and organizational commitment, increased intent to quit). These findings support past studies, which have shown that feelings of job insecurity may be associated with more serious physical conditions such as high blood pressure (e.g., Burchell, 1994) and the occurrence of ischemic heart disease (Siegrist, Peter, Junge, Cremer, & Siedel, 1990).

Despite the importance of studies that have examined the direct impact of job insecurity on employee health, there is evidence that the impact of job insecurity on employee health may also be indirect. For example, research by Probst (e.g., Probst, 2002, 2004, 2005) suggests that one of the immediate consequences of job insecurity is a decrease in concerns about safety among employees, particularly in organizations where there is not a positive safety climate to begin with. In other words, employees who are preoccupied with being laid off may not pay as much attention to safety procedures and thus may put themselves and other employees at risk.

More recently, it has also been shown that feelings of job insecurity may potentially contribute to a negative interpersonal climate within organizations. Gopalkrishnan (2010), for example, found in a sample of nurses that job insecurity was positively correlated with the experience of workplace incivility. Since this study was cross-sectional, it cannot be determined whether job insecurity led to higher levels of incivility or vice versa; however, these findings suggest an interesting indirect causal link between job insecurity and employee health. That is, feelings of job insecurity may lead to higher levels of interpersonal stressors in the workplace (to be discussed in greater detail later), which eventually negatively impacts employee health.

Future research on job insecurity should be aimed at both disentangling this causal chain linking job insecurity and employee health, as well as examining interventions designed to help employees cope with job insecurity. Some research has found, for example, that communication with employees about the reasons for layoffs tends to decrease feelings of injustice (see Brockner & Greenberg, 1990). However, it is less clear whether this type of intervention also has implications for employee health. Researchers would also do well to further clarify the job insecurity construct. As stated above, feelings of job insecurity may be due to perceptions of poor individual performance, yet relatively little is known about whether feelings of job insecurity due to poor performance have a different effect on employees compared to job insecurity based on the threat of layoffs.

Work–Family Conflict

While work is an important part of most people's lives, it is certainly not the *only* part of their lives. For most people, family represents the other primary domain of life, and thus work and family collectively represent the bulk of most people's time and activities. In an ideal world, people would be able to compartmentalize the demands of both work and family so that each does not spill over into the other. However, in some cases the demands of work make it more difficult for a person to fulfill his or her family demands; this is known in the literature as *work-to-family* conflict (Bellavia & Frone, 2005). In other cases, the demands of family make it more difficult to fulfill work demands; this is known as *family-to-work* conflict. It has also been shown that "demands," be they work or family, may be time-based, emotion-based, and strain-based.

While research on work–family is relatively recent compared to some areas of occupational health and safety, a considerable amount of research has been accumulated, so much so that work–family conflict has been the subject of several comprehensive qualitative reviews and meta-analyses (e.g., Bellavia & Frone, 2005; Byron, 2005; Kossek & Ozeki, 1998), including the chapter by Allen in this volume. Considering these works collectively, a very clear conclusion can be drawn: Both forms of work–family conflict are associated with negative effects on the mental and physical health of employees. It can also be concluded that one of the major reasons for these effects is the competing time demands that are associated with each of the life domains, and as a result of the distress associated with these time demands, people tend to engage in behaviors that are detrimental to their health.

For example, high stress, which presumably goes along with work–family conflict, is associated with poor dietary habits (Greeno & Wing, 1994). It has also been shown that those with high levels of work–family conflict tend to show decreased compliance with safety regulations (Cullen & Hammer, 2007).

Given this general conclusion that work–family conflict is negatively associated with mental and physical health as a starting point, however, if one delves a little deeper into the work–family literature, there are many factors that qualify this general conclusion. For example, the relation between both forms of work–family conflict is moderated by factors such as the work–family climate of an organization (Allen, 2001), as well as individual coping mechanisms such as time management (Adams & Jex, 1999). The most important factor that may mitigate the negative health-related effects of work–family conflict, however, is the level of flexibility and understanding of an employee’s immediate supervisor (Behson, 2002). This is because even when organizations have formal programs to help employees balance work and family demands, the extent to which employees are able to utilize such benefits is at least partially up to the discretion of individual managers.

In addition to investigating moderator variables, two relatively recent developments in work–family conflict research are also worth noting. First, researchers have begun to recognize that despite the considerable time demands that work and family domains exert on people, these demands are not always conflicting. In fact, it is possible for these two domains to *complement* each other. For example, the organization and planning skills required of a manager may help to keep things running more smoothly at home. Conversely, the understanding and patience required as a parent might help a manager to more effectively mentor his or her subordinates and resolve coworker conflict. Hanson, Hammer, and Colton (2006) recently examined this construct empirically (called *work–family facilitation*) and have found promising results—namely, that positive work–family facilitation is positively related to employee health. More research, however, is needed both to clarify the nature of this construct and to examine ways that organizations and individual employees can impact it.

A second recent development in the work–family conflict literature is the realization that the underlying issues leading to work–family conflict (e.g., the competing time demands of two role domains) are not exclusive to married people with school-aged children. For example, people with adult children may still have demands associated with elderly parents. In addition, people who are single may at

times have difficulty balancing the demands of work with other activities such as spending time with friends, pursuing hobbies and other interests, as well as being involved in their communities.

Because of this recognition, some have begun to use the more inclusive term *work/nonwork conflict* instead of *work–family conflict*. This makes a great deal of sense for a couple of reasons. First, despite the fact that parenting young children exerts considerable time and emotional demands, these represent only one type of nonwork demand that employees face. By focusing only on the demands of parenting, both researchers and organizations are looking at the construct much too narrowly. Second, broadening the concept to work/nonwork conflict opens up a number of interesting research possibilities. In fact, there has been some research on employees with elder-care responsibilities (Lee, Walker, & Shoup, 2001), but more research is needed to examine how employees balance the demands of work with other nonwork activities and obligations such as friends, hobbies, and community involvement, to name a few (Frone, 2003).

Role Stressors

If one were to go on the basis of sheer volume, there has been more written about role stress in the psychologically based occupational health and safety literature than any other topic. Given the sheer volume of work on role stressors, in this section we provide a very general overview of the types of role stressors, as well as summaries of notable meta-analyses that have summarized relations between role stressors and employee health. Readers interested in more in-depth coverage of role stressors are encouraged to consult a recent review by Beehr and Glazer (2005).

The foundation of role stressors is actually sociological role theory (Merton, 1957). *Role theory* simply states that a “role” is a set of behavioral expectations, and all people have certain “roles” that they plan in life. Two of the major tasks that people face in life are both clarifying those multiple roles, as well as balancing the demands associated with the various roles they play. An important corollary of this general proposition is that these processes of clarifying role demands and balancing potentially competing role demands also take place *within the same role*. Applied to the workplace, this suggests that for any given employee two major tasks are (a) clarifying the nature of one’s work responsibilities, and (b) attempting to balance work responsibilities that appear to be incompatible.

Before we describe the different types of role stressors and their effects on employee health, it is important to

keep in mind the “role-sending” process (King & King, 1990). Specifically, the underlying assumption behind the seminal work on role stressors (Kahn, Wolfe, Quinn, Snoeck, & Rosenthal, 1964) was that this process was largely *social* in nature. That is, while organizations do have some formal mechanisms (e.g., job descriptions) to help employees define their role requirements, these only lay the foundation for employees to define their role requirements. Because of this, formal mechanisms such as job descriptions are supplemented by both formal and informal communications with “role senders,” or those who help to define the employee’s role. For obvious reasons, the most important role sender is typically one’s immediate supervisor, but employees also receive role-related communications from coworkers, and in some cases, even customers. Based on all of this information an employee defines his or her work role over time.

Given the social nature of the role-sending process, and the fact that *multiple* role senders are providing the information, it is an imperfect process. One problem that may occur in the role sending process is that role senders may not provide clear information, which results in a stressor known as *role ambiguity*. Role ambiguity is a stressor that came out of the original research on role stress (e.g., Kahn et al., 1964) and simply reflects a lack of clarity regarding one’s job responsibilities and performance expectations. Attempts to measure role ambiguity (e.g., Rizzo, House, & Lirtzman, 1970) have, to a large extent, focused on ambiguity surrounding job responsibilities. More recent attempts to measure role ambiguity (e.g., Breaugh & Colihan, 1994) have included performance expectations, and have broadened the construct to include ambiguity with regard to scheduling.

Another consequence of the role sending process, particularly due to the fact that multiple role senders are communicating role expectations, is that these role senders may not be on the “same page” in terms of the role demands they communicate (King & King, 1990). One consequence of this is that an employee who is in contact with multiple role senders may simply be overwhelmed by the role demands that are communicated. This stressor is known as *role overload*. Despite its potential importance, particularly with respect to health, very little research has been done on role overload (see Beehr, Jex, Stacy, & Murray, 2000). This is largely due to the overlap between role overload and workload (covered in a subsequent section of this chapter), and simply the fact that other role stressors have received much more attention.

In addition to the sheer volume of role demands, there may be situations where the demands of various role

senders are not compatible. For example, in academic settings, students often want faculty to devote considerable time to them, while at the same time academic departments demand that faculty also spend considerable time publishing and writing grants. Unfortunately, since time is a finite resource, the more time one spends with students the less time one has for publication and grant-writing activities, and vice versa. This situation is known as *role conflict* and has been studied nearly as extensively as role ambiguity.

Research on role ambiguity and role conflict, which has taken place over nearly a 50-year time span, has shown that both of these stressors are negatively associated with psychological and physical health. Two primary meta-analyses (e.g., Abramis, 1994; Jackson & Schuler, 1985) have produced relatively similar conclusions. That is, both role stressors are associated with psychological strains such as job dissatisfaction, anxiety/tension, and subclinical depressive and anxiety symptoms. These meta-analyses have also revealed that role stressors are also positively related to somatic symptoms, which suggests that both may have a deleterious effect on physical health. However, in all of these meta-analyses, role stressors tend to be more strongly related to psychological outcomes than they are to physical outcomes. This may be due to the fact that both role stressors and psychological outcomes are measured with self-reports and thus share a common method (e.g., Spector, 1987). A more substantive explanation is that there are many factors (e.g., genetic predispositions, lifestyle, etc.) other than work-related stressors that determine physical health, so the amount of variance possible to explain is likely to be smaller compared to psychological variables.

In addition to examining the main effects of role stressors, researchers have for many years examined variables that moderate relations between role stressors and employee health outcomes. While an exhaustive coverage is beyond the scope of this chapter, there are some that have been frequently examined over the years, and we examine these in a little more depth. One of these is *social support* or the extent to which friends, family, colleagues, or one’s supervisor provide moral support or encouragement when one is experiencing work-related stressors (Cohen & Wills, 1985).

Social support research has a long (and somewhat mixed) history in occupational stress research (Beehr, 1995). That is, researchers have examined social support from many sources as a moderator or “buffer” of relations between many types of stressors and many types of strains. Viswesvaran, Sanchez, and Fisher (1999)

conducted a meta-analysis of the social support literature and concluded that the true amount of variance explained by moderator effects is approximately 2%, which suggests that social support does exhibit a moderator effect but it is not a strong effect. Keep in mind, however, that the meta-analysis conducted by Viswesvaran et al. (1999) was not confined to studies examining role stressors. However, according to Beehr and Glazer (2005), if one were to look exclusively at role stressors, it is likely that the amount of variance explained by such moderator effects would be very similar.

A second potential moderator of relations between role stressors and employee health, and one that has received wider empirical support than social support in the occupational stress literature, is *job control*. While job control has at times been defined in multiple ways (e.g., Hackman & Oldham, 1980; Karasek, 1979; Spector, 1986), which has made for some confusion in the literature, it is essentially the extent to which employees have discretion over important aspects of their jobs, such as how their job tasks are performed, scheduling of job tasks, and their work schedule. Like social support, job control has a long history as a moderator variable in occupational stress and health research (Spector, 2002), though relatively few studies have investigated job control as a moderator of relations between role stressors and employee health outcomes (e.g., Beehr, 1976; Ganster, Fox, & Dwyer, 2001; O'Driscoll & Beehr, 2000). Furthermore, much like social support, the moderating effects of job control have been mixed.

In recent years research has provided important insights to clarify why the moderating effects of job control have been mixed. For example, Jimmieson (2000) found that job control moderated the relation between role conflict and the depersonalization dimension of burnout only for employees who reported high levels of self-efficacy (e.g., they believed they were capable of performing their jobs well). This study, along with research examining other stressors (e.g., Schaubroeck & Merritt, 1997), suggests that job control can be a potent moderator of relations between role stressors and employee health outcomes—this supports past research on job control and, to a large extent, makes intuitive sense. However, it is also the case that job control is a resource that not every employee necessarily *wants* or is *able to benefit from*.

A final moderator, and in some ways the most intuitive, that has been examined is *tolerance for ambiguity*. The basic idea is that systematic differences exist in people regarding the extent to which they “perceive

(i.e., interpret) ambiguous situations as sources of threat” (Budner, 1962, p. 29). One would assume that people who have a low tolerance for ambiguity would react more negatively to role ambiguity compared to those who have a higher tolerance. Frone (1990) examined this hypothesis in a meta-analysis of seven studies and found that relations between role ambiguity and a number of outcomes were generally stronger for those with a lower tolerance for ambiguity. Despite the fact that this meta-analysis was based on a small number of studies, the implication is that ambiguity in role requirements is much more stressful to some people than to others.

Workload

Like many variables in occupational health and safety research, workload is a deceptively simple term. Certainly one way we can view an employee's workload is in quantitative terms; that is, the number of hours worked, number of classes taught, number of clients served, or number of projects worked on. Quantitative indices of workload have the advantage of objectivity, and as was shown in the previous section on work hours and shiftwork, both of these may have important effects on both an employee's physical and psychological health and well-being.

Relying solely on quantitative indices of workload unfortunately provides an incomplete picture of this important variable for a number of reasons. First, despite the fact that employees may have objectively similar job demands, they may *perceive* those demands differently. For example, in the development and validation of a perceived workload scale, Spector and Jex (1988) have found considerable variability even in samples of employees essentially performing the same work (e.g., Spector, Dwyer, & Jex, 1988). This suggests that workload is not completely objective; that is, there are some perceptual and psychological processes involved that may make employees perceive the same objective amount of work differently.

Second, research has shown that employees do not view their workload strictly in terms of “amount” but rather also view it in terms of the difficulty level. For example, in the occupational stress literature (Beehr, 1995), a distinction has at times been made between *quantitative* and *qualitative* work overload. Quantitative work overload is simply having too much volume of work to do in a given time period. Qualitative workload, however, represents an employee's perception of the difficulty of work he or she is required to perform. An employee who is qualitatively overloaded may have ample time to perform his or her work, yet still feel that the work is too

difficult given his or her skills or training (Ivancevich, Matteson, & Preston, 1982).

Another complicating aspect of workload is that for most jobs it is not necessarily a constant. In retail, for example, the volume of work employees have to do increases considerably in the month prior to Christmas; in academia, the volume of work employees have to do increases immediately prior to the end of an academic semester and decreases considerably in the summer months. Note, however, in both of these examples the changes in workload are due to the inherent cyclical nature of the work performed by each of the organizational types. Thus, to a large extent these changes in workload are more or less *predictable*.

It is also the case that there are certain occupations where the workload is not at a constant level, and it is not nearly as predictable. Firefighters, emergency workers, and military personnel may go through considerable periods of time where there is very little “action” and where their tasks are relatively mundane (e.g., routine equipment maintenance or training). In contrast, at other times the work may become very intense for hours, days, or even longer periods of time. Thus, another dimension of workload that might have important implications for employees, and that makes workload even more complex as a variable, is that we can also look at the variability and predictability of workload as two dimensions that could potentially impact employee health. Furthermore, it has been shown that workload variability is associated with decrements in employee health (Beehr et al., 2000).

Given the level of complexity of workload, there have not been a great deal of studies to examine all of the various dimensions of workload. If we look at workload as a psychological or perceptual variable, however, the most comprehensive study of the health-related effects of workload is a meta-analysis by Spector and Jex (1998) in which they summarized 18 studies with a total sample of 3,868 employees, which examined the relationship between perceived workload and a number of psychological and physical health outcomes. The results of this study are summarized in Table 23.1. As can be seen, this perceived workload measure is positively related to a number of health-related indices including anxiety, frustration, doctor visits, and physical health symptoms. It is also interesting to note, based on this meta-analysis, that the corrected correlation between perceived workload and work hours was .33. This suggests that employees’ perceptions of workload are based on more than just the amount of time one spends in the workplace.

TABLE 23.1 Corrected Correlations Between Quantitative Workload and Health Indicators

Health Indicator	QWI
Anxiety	0.40
Depression	0.21
Job Satisfaction	-0.17
Intent to Quit	0.24
Doctor Visits	0.10
Physical Symptoms	0.27

Note: QWI = Quantitative Workload Inventory; Adapted from: Spector, P.E., & Jex, S.M. (1998). Development of four self-report measures of job stressors and strain: Interpersonal Conflict at Work Scale, Organizational Constraints Scale, Quantitative Workload Inventory, and Physical Symptoms Inventory. *Journal of Occupational Health Psychology*, 3, 356–367.

Interpersonal Stressors

While the work environment provides employees with the opportunity to develop meaningful interpersonal relationships with others, it is also the case that interpersonal relationships have the potential to negatively impact employee health. Interpersonal conflict at work is a significant stressor that has been associated with poor employee performance and with negative health and safety outcomes (Einarsen, Hoel, Zapf, & Cooper, 2003; Haugh, Skogstad, & Einarsen, 2007; Neuman and Baron, 1997; Tuckey, Dollard, Saebel, & Berry, 2010). Conflict on the job may involve clients or customers, coworkers, or supervisors, or the source may be a complete stranger or an acquaintance, spouse, or partner of the employee who gains access to their place of employment.

The degree of interpersonal conflict in a given workplace also varies considerably. Behaviors may range from mild rudeness or incivility to more intense forms of workplace aggression such as bullying, emotional abuse, or physical attacks (Andersson & Pearson, 1999; Baron & Neuman, 1996; Keashly & Harvey, 2006; Rayner, Hoel, & Cooper, 2002). Some researchers argue that what may seem like innocuous rude or uncivil behaviors may spiral into more incivility and hostility in the workplace, creating a vicious cycle that may escalate into more overt acts of aggression (Andersson & Pearson, 1999; Cortina, Magley, Hunter, & Langhout, 2001). Acts of aggression can be physical or nonphysical, and they are intended to harm workers in their workplace or in situations related to work (Neuman & Baron, 1997). The term psychological aggression refers to nonphysical behaviors that are meant to cause distress or harm to the target (Keashly & Harvey, 2006). Bullying, which may involve both physical and nonphysical forms of aggression, has been very strictly defined in terms of the persistence,

frequency, and duration of negative behaviors directed at one or more than one person at work (Einarsen, et al., 2003; Lutgen-Sandvik, Tracy, & Alberts, 2007). A constellation of behaviors is called bullying only if the negative actions are persistent, and occur repeatedly, rather than single isolated events that only happen occasionally (Einarsen, et al., 2003; Rayner, et al., 2002).

Workplace aggression includes a variety of behaviors that are intended to humiliate, intimidate, threaten, or undermine a worker's performance or his or her personal or professional reputation (Rayner, et al., 2002; Einarsen, et al., 2003; Keashly & Harvey, 2006). The types of behaviors include social isolation, derogatory or offensive remarks, gossip, sabotage, insults, non-inclusion, withholding information necessary to do the job, and physical actions that are perceived as threatening or intimidating (Keashly & Harvey, 2006). For the most part, workplace aggression is typically passive and nonphysical in nature, which may make the targets of the behaviors uncertain that they are experiencing a harassing behavior in the first place due to the subtle nature of the actions, and this is one of the reasons why it is difficult to assess the true extent of the problem. Further, most acts of bullying are not reported by those being victimized, and in some professions these types of behaviors are considered "part of the job" (Stagg & Sheridan, 2010).

It is difficult to estimate the prevalence of workplace aggression for several other reasons as well. The prevalence of bullying and psychological aggression depend heavily upon how the terms are defined, how the investigator asks about the experiences, the study timeframe that is used, and the study sample itself (Einarsen et al., 2003; Keashly & Harvey, 2006). Estimates of workplace aggression range from 27% to 59% and even higher, depending upon the study parameters. Studies indicate that 10% to 14% of workers report being bullied at work, and it may be as high as 40% to 50% if those who witness an act of bullying are included (Keashly & Harvey, 2006). Workplace aggression may occur at all levels in an organization including management, and men and women both may be targets as well as aggressors.

Many factors have been associated with workplace aggression and bullying. These include work organization factors such as lack of job control and decision-making power, role conflict, leadership style, poor organizational climate, low levels of social support from coworkers or supervisors, and high workload or job demands (Einarsen, et al., 2003; Keashly & Harvey, 2006). Changes in the workplace or economic climate such as job insecurity, downsizing, or organizational restructuring have also been

related to workplace aggression (Einarsen, et al., 2003; Keashly & Harvey, 2006; Rayner, et al., 2002). Individual characteristics of the actors in the workplace may also be associated with workplace aggression. Organizational culture and perceptions of justice also may play an important role in whether employees feel free to engage in aggressive behaviors at work (Griffin, 2010).

Workplace aggression is harmful to employees and to the organization itself. Experiencing directly or even witnessing aggressive behaviors at work have been related to a host of adverse mental health outcomes, including anxiety, depression, alcohol and substance abuse, feelings of helplessness, and in severe cases, post-traumatic stress disorder (Einarsen et al., 2003). Physical health outcomes have also been reported by those experiencing or witnessing bullying, including sleep disorders, headaches, and gastrointestinal disorders (Einarsen et al., 2003; Haugh, et al., 2007; Merez, Drabek, & Mościcka, 2009; Niedhammer, Davis, Degioanni, Drummond, & Philip, 2009), and recent studies suggest a link between exposure to workplace aggression and cardiovascular disease (Tuckey et al., 2010). Bullying and workplace aggression are also costly to the organization in terms of reduced job performance and productivity, lower job satisfaction, reduced organizational commitment and motivation, nonparticipation in professional activities, and increased intent to leave, sick time, and absenteeism (Einarsen et al., 2003), as well as recruitment and replacement costs (Stagg & Sheridan, 2010). Being the victim of or witness to workplace aggression also impacts family relationships, spilling over into the employee's home life. On a more positive note, high levels of social support in the organization and at home have been shown in some studies to buffer the negative effects of workplace bullying and aggression (Schat & Kelloway, 2003).

Workplace aggression and bullying are most prevalent in law enforcement, health care, and service delivery occupations (Felblinger, 2008; Johnson, 2009; Rosenstein and O'Daniel, 2005; Tuckey et al., 2010)—this includes police and correctional officers, nurses, nurses' aides, home health care providers, social workers, and those involved in providing retail or customer service.

Employee Safety

In most countries organizations are mandated by law to provide employees with a healthy and safe work environment; for example, in the United States occupational safety legislation was enacted in 1970. While we have not completely ignored safety to this point in the chapter, the

focus has largely been on employee health. In this section, however, we focus exclusively on employee safety. In order to cover employee safety, we focus on what have become standard topics in the psychologically based literature: namely, physical hazards in the work environment, organizational safety climate, and finally, organizational interventions to improve employee safety.

Before delving into employee safety, a number of points need to be made. First, the basis for safety in any organization is the accurate measurement of safety indices such as number of accidents, days lost from work, and, even in recent years, “near misses” or incidents where an employee almost has an accident (Clark, Rockett, Sloane, & Aiken, 2002). In most countries organizations are required by regulatory agencies to collect safety data. The importance of measurement goes far beyond legal compliance, however, because it is the only way that an organization can get a true picture of its level of safety performance, and perhaps even more important, assess the impact of safety interventions (discussed later in this section).

A second point worth noting is that safety legislation applies to *recognized* hazards in the work environment (Smith & Carayon, 2011). This is an important point because employees in an organization may appear to be working in a safe environment, yet there may be unrecognized physical hazards or work procedures that may ultimately result in injuries. Thus, an organization’s workforce may be “safe” at any one moment in time yet still be at risk of injury. This point has emerged in recent literature on safety climate (discussed later in this section) where researchers have distinguished between *safety compliance* and *safety participation* (Neal, Griffin, & Hart, 2000). Safety compliance refers to the following of established safety rules and procedures—rules and procedures that are based on recognized hazards in the work environment. Safety participation, however, represents efforts on the part of employees to improve safety; inherent in this definition is the discovery of previously unrecognized hazards in the work environment. The overall point is that safety is more than simply following established rules and procedures; it is a desire to constantly improve safety as well.

A third and final point is that employee safety is truly an interdisciplinary field. Specifically, safety researchers and practitioners are trained in a wide range of fields such as engineering, medicine/nursing, public health, human resources, industrial hygiene, audiology, ergonomics/human factors, and industrial–organizational (I-O) psychology, to name a few. To a certain extent, this wide range of disciplines simply reflects the wide range

of workplace hazards present in many work settings. However, it also reflects the complexity of many of the issues surrounding safety in organizations, and given that complexity, psychology stands out as a very key discipline in safety research and practice. That is, fields concerned with elimination of physical hazards in the work environment such as safety engineering or industrial hygiene are often unsuccessful in the elimination of such hazards or protection against such hazards because of issues that are inherently behavioral in nature. In the construction industry, for example, safe work practices exist but in some cases are not followed because of the pressure of deadlines (Mohamed, 2002). Thus, while we are certainly not saying that psychology is the most important discipline in safety research and practice, it is one that interacts with virtually all other disciplines.

Physical Hazards in the Work Environment

Given the diversity of organizations and job types, there are literally thousands of potential physical hazards in the work environment (Smith & Carayon, 2011). Furthermore, NIOSH and other organizations such as the National Safety Council and American Industrial Hygiene Association have attempted to document the most common physical hazards in the work environment. Given this wide variety of physical hazards, we make no attempt to be comprehensive in our coverage but rather cover (a) those that have been most heavily researched, and (b) those that most clearly have psychological antecedents or consequences.

According to Smith and Carayon (2011), physical hazards in the work environment can be classified into eight distinct types, and these are presented in Table 23.2. As can be seen, the first category, Physical Agents, such

TABLE 23.2 Summary of Physical Work Hazards

Hazard	Examples
Physical agents	Heat and noise
Powered mechanical agents	Machinery and tools
Nonpowered mechanical agents	Hammers, axes, and knives
Liquid chemical agents	Benzene and toluene
Powdered chemical agents	Pesticides and asbestos
Gaseous or vaporous chemical agents	Nitrous oxide and carbon monoxide
Biological agents	Bacteria and viruses
Other hazards	Wet surfaces, unguarded floor openings, job stress, unsafe behavior of others

Note: Adapted from: Smith, M.J., & Carayon, P. (2011). Controlling occupational safety and health hazards. In J.C. Quick and L.E. Tetrick (Eds.), *Handbook of occupational health psychology* (2nd ed., pp. 75–94). Washington, DC: American Psychological Association.

as heat and noise, represents some very common physical hazards for blue-collar jobs but certainly could be present in a white-collar work setting (though for shorter periods of time). It is interesting to note that although these hazards certainly have the potential to negatively impact employees physically, it has also been shown in the social psychological literature (e.g., Anderson, Deuser, & DeNève, 1995; Westman & Walters, 1981) that these physical agents may also impact employees psychologically. The positive aspect of this category is that it is relatively easy to reduce or eliminate it by using engineering controls.

The next two categories, Powered and Non-Powered Mechanical Agents, have to do with the design and operation of the machinery or tools with which employees work. Like the first category, this physical hazard is typically associated with blue-collar jobs. The one exception, however, would be clerical employees or call center employees who spend long periods of time working on computers and, as a result, develop musculoskeletal disorders (Seppala, 1995). Also, like the first category, this is a type of physical hazard that can be greatly reduced or even eliminated through the design or modification of equipment. There may be instances, though, where either equipment cannot be modified or the cost of doing so would be prohibitive. In these cases, a management decision would have to be made regarding things such as job rotation or rest breaks in order to allow people to be exposed to such conditions without being harmed.

The next four categories (Liquid Chemical Agents, Powdered Materials, Gaseous and Vaporous Chemical Agents, and Heavy Metals) are again physical hazards that are specific to certain industries and job types; mainly in manufacturing, mining, and chemical processing. It is certainly possible that white-collar employees (in laboratories, for example) could be exposed to such hazards, though their level of risk is obviously much lower. As with the previous category, these hazards can typically be reduced or eliminated entirely through engineering interventions such as improved ventilation and air filtration systems (Fisk & Rosenfeld, 1997). The psychological aspect of these hazards lies mainly in training employees to *recognize* situations where they might have the potential for exposure to them and to use proper procedures (e.g., safety equipment) when the situations arise. There is also evidence that in addition to causing physical disease, exposure to hazardous substances may cause psychological trauma as well (e.g., Ford, Schnurr, Friedman, Green, Adams, & Jex, 2004).

The final category is obviously meant to cover physical hazards that weren't addressed in the other categories.

Job stress has already been covered in a previous section, so that does not warrant further discussion. Two hazards in this category, however, seem very important and thus would seem to require further comment. The presence of wet or slippery surfaces is a very common workplace hazard, particularly in restaurants and grocery stores, and is the cause of many workplace injuries (Chang, Li, Filiaggi, Huang, & Courtney, 2008). Furthermore, engineers have come up with very effective solutions such as altering the soles of shoes in order to provide better traction on floors (e.g., Verma et al., 2010). There is still a psychological element to this hazard in that employees must be trained to recognize it and take steps to eliminate it (e.g., mopping grease from floors).

The other hazard worth mentioning, and clearly the most psychological in nature, is the unsafe behavior of others. While engineering controls can be used to eliminate many of the hazards in this section, there is no known way that unsafe behavior on the part of another coworker can be "engineered" out of the workplace. Therefore, what options are available to control this hazard? One obvious solution would be to make sure that employees are properly trained to do their work and that they understand safety procedures. Even in cases when organizations do this, however, this may not eliminate risky or unsafe behaviors on the part of employees. This is due to the fact that unsafe behavior may at least be partially due to personality traits (e.g., Hansen, 1989) or other factors such as substance use (e.g., Frone, 2006). In summary, then, there are clearly a large number of physical hazards in the workplace and in this section we have really only scratched the surface. The positive thing about physical hazards (if there can be one) is that many if not most of them can be reduced or even completely eliminated through engineering interventions. For example, machines can be designed so that they run more quietly and air filtration systems can be designed (or current ones altered) in order to eliminate harmful gases. In other cases, however, such hazards cannot be eliminated and therefore employees must be trained to either recognize such hazards or take steps (e.g., wearing safety equipment) to reduce them. Both of these issues are behavioral at their core and are thus things to which psychologists can (and in fact have) contribute. Psychologists may also contribute to reducing unsafe behavior of others through training and selection interventions.

Safety Climate

The term *organizational climate* is certainly not new to those in I-O psychology, organizational behavior, or organizational development. First coined by Litwin and

Stringer in the late 1960s (Litwin & Stringer, 1968) and later more fully developed by others (e.g., Reichers & Schneider, 1990), organizational climate simply reflects “shared perceptions” among employees of what it feels like to work in an organization. These shared perceptions can reflect many aspects of organizational life (e.g., rewards, nature of communication, nature of supervision, customer service, etc.); thus, in effect, there are many “climates” within an organization.

Zohar (2003b) defined safety climate as “shared perceptions with regard to *safety* policies, procedures, and practices.” (p. 125, italics in original). He goes on to state that despite the generality of this definition, safety climate is a very complex variable because it exists on many levels within organizations. That is, one can certainly point out the formal policies and procedures with regard to safety—what’s “on paper” as far as safety issues are concerned. It is also possible, though often less obvious, to capture the relative priority of safety in comparison to other organizational priorities. For example, when following proper safety procedures results in slower production, does an organization still follow proper safety procedures or do they “cut corners”? In some respects this reveals much more about an organization’s safety climate than written safety policies and procedures.

Another distinction, which was previously mentioned, that is typically made in the safety climate literature is between *safety compliance* and *safety participation*. Borrowed from the broader literature on job performance (e.g., Campbell, 1990; Organ, 1988), this is an important distinction because it recognizes that safety is about more than just following policies and procedures. Specifically, safety compliance simply reflects the extent to which employees follow formally established safety protocol. For example, in a hospital setting this would reflect the extent to which nurses follow formal procedures for disposal of used needles (DeJoy, Murphy, & Gershon, 1995). Safety participation, on the other hand, reflects the degree to which employees are motivated to look for ways to make the workplace safer. An example of this might be an employee developing a safer way to perform a task.

While safety compliance is clearly an important dimension of organizational safety climate, compliance alone does not necessarily lead an organization to a stellar safety record. As was aptly pointed out by Smith and Carayon (2011), regulations put forth by OSHA and other similar agencies state that organizations must protect employees from *known* hazards in the work environment. It stands to reason that established safety rules and procedures, which are developed largely in response to regulatory agencies,

are designed to protect employees only from known hazards in the work environment. Thus, employees that go no further than safety compliance are probably not going to be protected from new or previously unknown hazards in the work environment. However, if safety participation is also high, employees will be on the lookout for newer hazards and ways to better protect themselves against these hazards.

A second reason that safety compliance alone will not necessarily protect employees is that safety is often impacted by situational pressures. In the construction industry, for example, contractors are under tremendous pressure to finish buildings and other structures. As a result, use of proper safety procedures is often perceived as an impediment to project completion and thus employees may cut corners as a result (Mohamed, 2002). However, if safety participation in an organization is also high, employees might be less likely to do this because they view safety as a part of their jobs and a high organizational priority (Clarke, 2006).

Having defined safety climate, and discussed its dimensions, we now focus on what is perhaps the most important question: Does safety climate make a difference in the actual safety performance of organizations? Clarke (2006) performed what has to date been the most comprehensive meta-analysis on the relation between safety climate and safety performance in organizations (measured by accident involvement), and the results of her study suggest that the answer to this question is “Yes.” Specifically, she found that the corrected correlation between safety compliance and accident involvement ($r = 0.09$) was significantly weaker than the corrected correlation with safety participation ($r = 0.14$). Although not necessarily a surprising finding, this does provide empirical evidence that compliance–participation is not only important conceptually but may also have important practical implications for organizational safety records.

Another important finding in this meta-analysis was that study design was a moderator variable. Specifically, she found that studies that used a prospective design, where safety climate was measured prior to accident involvement, produced a stronger correlation than studies where a cross-sectional design was used. This suggests, though is certainly not definitive proof (e.g., Cook, Campbell, & Peracchio, 1990), that safety has a causal effect on accident involvement. Subsequent research (Beus, Payne, Bergman, & Arthur, 2010) has challenged this assumption, that is, suggesting that the level of accident involvement causes safety climate, so more research on this issue is undoubtedly needed.

The final issue with respect to safety climate, and one that has been mentioned in the previous section, is what *causes* organizational safety climate in the first place. This is an important issue, presumably because one of the reasons for studying safety climate is not only to document its effects but also to help organizations develop a more positive safety climate, and as a result improve their safety performance. Although there could be many causes of safety climate, including an organization's safety record itself (Beus et al., 2010), recent research suggests that the top management of an organization has a strong impact on the development of an organization's safety climate. For example, Barling, Loughlin, and Kelloway (2002) found in two separate studies that "transformational leadership" was negatively related to occupational injuries in two separate studies. Most importantly, however, they found that this relationship was mediated by safety climate, safety consciousness, and safety-related events. Transformational leaders are those who use mechanisms such as idealized influence, inspirational motivation, intellectual stimulation, and individualized appeals to motivate employees (Avolio, 1999).

Another factor that may potentially impact safety climate has to do with individual employees' perceptions of their jobs. As has been shown in many studies conducted over the years, employees tend to make a distinction between "in-role" and "extrarole" tasks (Campbell, 1990; Morrison, 1994). Given this distinction, it is logical, and in fact rational, that employees would place more emphasis on in-role tasks because performance on these typically serves as the basis for important decisions such as merit raises and promotion. Thus, to the extent that employees view safety behaviors as "in-role," they will probably be more likely to follow safety procedures and in fact may be willing to suggest ways to make the workplace even safer. Clark (2003, 2006) examined this issue in two occupational groups (food service workers, and nurses) and found differences in the extent to which these employees viewed safety as "in role" versus "extrarole." The implication of both of these studies is that organizations should try to emphasize that safety is a high priority, and in fact an integral part of their job.

Safety Interventions

As was stated earlier, the study of safety in organizations has a long history (though not in psychology), so a comprehensive review of safety interventions is clearly beyond the scope of this chapter. Further, since many safety interventions involve physical alterations to the work environment that are essentially out of the control

of the employee, in this section we review what might be termed "employee-focused" safety interventions. These involve interventions that are aimed primarily at altering the safety-related attitudes and behaviors of employees, although the first one we discuss (selection) is aimed primarily at preventing potentially unsafe people from entering the workplace.

As was pointed out earlier, many years of research have failed to produce a definitive profile of the "unsafe employee" (Hansen, 1989), and thus the search for individual difference predictors of accident involvement was essentially abandoned. However, over the past 25 years there have been a number of theoretically based studies examining the relationship between individual difference variables and accident involvement. This literature was recently summarized in a comprehensive meta-analysis by Christian, Bradley, Wallace, and Burke (2009). These authors showed that a number of individual difference variables predicted both accident involvement and workplace injuries. The strongest of these appeared to be conscientiousness, internal locus of control, risk taking, and neuroticism. More specifically, employees who are highly conscientious, believe they have control over outcomes in the workplace, do not take unnecessary risks, and who have a high level of mental stability tend to be involved in fewer accidents and report fewer occupational injuries. Interestingly, though, this meta-analysis also investigated situational predictors of accident involvement and occupational injuries and, for the most part, the situational predictors were stronger than the individual difference predictor; human resource management practices related to safety in particular stood out as a strong predictor of accidents. More specifically, selecting employees who were likely to be safe, providing high-quality safety training, and rewarding employees with exemplary safety records was associated with lower accident rates.

What, then, can be concluded about individual differences and safety, and more importantly, what are the practical implications of those conclusions? First, selection alone is not a viable intervention for improving safety in an organization. The findings of Christian et al. (2009) show clearly that situational variables are more strongly related to safety than individual differences. Second, if an organization were to use selection as a method of improving safety, the best place to start would be with conscientiousness. Not only was conscientiousness the strongest predictor of accident involvement, it has been shown to predict performance over a wide variety of jobs (Barrick & Mount, 1991) and has been shown to predict deviance (Ones, Viswesvaran, & Schmidt, 1998).

In addition to using personality traits such as conscientiousness in the selection process, organizations can also potentially improve safety by screening out applicants with substance use problems. A good deal of research, both in the workplace (e.g., Normand, Salyards, & Mahoney, 1990) and outside of the workplace (e.g., Cherpitel, 2007), has shown a clear connection between substance use and accidents and injuries. Given this, and the myriad other problems associated with employee substance use (e.g., higher absenteeism, increased health care costs), organizations may want to take steps to screen out employees with a history of substance abuse problems.

While the goal of screening applicants is relatively clear cut, what is much more complicated (and, in fact, controversial) is how this is done. The most common method is the use of preemployment drug screening through urinalysis, although organizations could use other methods such as background checks. Although there is evidence that urinalysis can be used successfully to screen out applicants with substance use problems (McDaniel, 1988), it is certainly not without problems. While there is evidence that *most* people see a drug screen as a reasonable step for organizations to take when hiring for jobs where safety is crucial (e.g., bus drivers, airlines pilots; Murphy, Thornton, & Reynolds, 1990), it is still possible for an organization to turn off potential applicants by using drug screening. The other problem with drug screening, and perhaps the most important one, is that of *construct validity*. In other words, if an applicant tests positive for marijuana, this could mean that this person is a habitual user and as a result has a level of cognitive impairment that could impact his or her safety behaviors on the job. Of course, a positive test could also mean that the applicant partakes very sporadically, and thus has little or no cognitive impairment (though using marijuana fairly close to a preemployment drug test may in itself be an indication of poor judgment) and thus his or her level of safety would not be negatively impaired at all.

As mentioned above, organizations may also use background checks to screen out potential substance abusers. This is based on the relatively simple, yet time-tested principle that “past behavior predicts future behavior.” As is the case with drug screening, however, using background checks can also be controversial. If an organization were to contact an applicant’s former employer and inquire about substance use issues, this raises important legal issues related to invasion of privacy and potentially defamation of character (Ryan & Laser, 1991). It also raises the issue of whether an applicant’s former employer

would even divulge such information; in many cases organizations may be very hesitant to release such information due to potential legal actions. Therefore, while we do acknowledge that background checks could potentially be used to screen out substance users, organizations must be *very* careful about how they obtain background information and should do so only in consultation with legal counsel.

Assuming for the moment that an organization has done everything possible to hire employees that have a high probability of being safe on the job, what can be done once employees are on the job? One of the most common interventions, most likely due to its simplicity, is *safety promotion*. Safety promotion is defined as the use of persuasive messages within an organization to remind employees of the importance of safety, or perhaps promote some safety-related achievement (e.g., number of days without an injury; Rosen & Jansson, 2000). In many organizations walls are decorated with posters reminding employees of the importance of safety, or coffee mugs have slogans promoting safety.

Despite the widespread use of safety promotion in organizations, there is relatively little empirical evidence that these types of interventions have any more than a negligible effect on tangible safety indicators such as number of accidents or lost work days. Perhaps to understand why safety promotion does not have a stronger effect, one need only look at basic social psychological research on persuasive messages (e.g., Petty & Caccioppo, 1986). While a complete coverage of this literature is beyond the scope of this chapter, it has been shown that a number of factors impact whether a persuasive message results in behavior change—nature of the message (e.g., content, length, amount of information conveyed), credibility of the source, and emotions evoked by the persuasive message. Generally speaking, persuasive messages are most successful when they are relatively brief, convey specific information about how to change behavior, come from credible sources, and do not evoke extreme emotions. Posters and coffee mugs containing persuasive messages related to safety have some of these attributes (e.g., brevity, and perhaps source credibility), but they are severely lacking in specificity. Perhaps the most that can be said about safety promotion is that it is a relatively low-cost way of increasing employees’ *overall awareness* of safety in the workplace, but in the absence of other interventions probably has little impact on any tangible safety indicator.

Given the limitations associated with safety promotion, a more tangible step toward improving safety is helping

employees acquire the knowledge and skills they need to be safe. Thus, another potential intervention that organizations might use to improve safety is *training*. Christian et al. (2009) found that although employee *safety knowledge* was not a strong predictor of actual accident involvement, it actually turned out to be the strongest overall predictor of composite safety performance (e.g., accident involvement, lost work time, etc.). This suggests that employees who have a high level of safety knowledge are also likely to show better overall safety performance in the organization. Given that relationship, one way organizations could improve safety is by thoroughly training employees in safety policies and procedures. While the specifics of such training are obviously beyond the scope of this chapter, this suggests that in many cases employees are not safe because they do not know how to be safe.

Even if employees have the knowledge and skills required to be safe, accidents still may occur because employees are not properly motivated to use this knowledge to prevent accidents. Therefore, a third potential intervention to improve safety is the use of incentives or other means, such as goal setting, to motivate employees to engage in safe behaviors (Komaki, Heinzmann, & Lawson, 1980; Ludwig & Geller, 1997). These types of interventions, particularly the use of behavior modification, have a strong theoretical foundation and have been shown to be effective in a wide variety of settings (Krause, Seymour, & Sloat, 1999; Sulzer-Azaroff, 1987).

Despite the effectiveness of interventions designed to modify the safety-related behaviors of employees, there are some limitations to this approach. For one, this approach typically focuses on employee behaviors relative to *known* hazards in the work environment. Thus employees trained to engage in safe behaviors are not protected from new or novel workplace hazards. A second problem is that interventions designed to modify safety-related behavior are typically aimed at relatively simple types of behaviors. For example, in reviewing research on behavior modification and goal setting, in most cases the targeted behaviors are relatively low on complexity (e.g., driving safely, lifting properly, wearing hearing protection). Granted, these are important safety-related behaviors, however, in more complex environments (e.g., a surgical suite or a nuclear power plant, for example) the behaviors necessary to be safe are also inherently more complex. Using incentives is much more difficult to do with employees who perform much more mentally complex tasks because in these types of jobs the distinction between safe and unsafe is not always so clear.

Another limitation of incentives, and perhaps goal setting as well, is that these types of interventions may fail because of competing incentives within the work environment; that is, there are often built-in incentives in the work environment that either discourage safe behavior or actually *encourage unsafe behavior*. Perhaps the best example of this is the case of pizza delivery drivers. While an organization might take steps to reward drivers for having safe driving records (Ludwig & Geller, 1997), such an intervention may not be effective if the drivers are paid on the basis of the absolute number of pizzas delivered. This perceived tradeoff between safety and productivity is a common dilemma in many types of organizations (e.g., construction, farming, meat packing), but it is one that organizations must eventually grapple with if they truly want to improve safety (Humphrey et al., 2004; Zohar, 2003b).

Perhaps the most the most effective way to improve safety in organizations, though in many ways the most difficult, is to change the organizational safety climate. This is difficult for a number of reasons. First, it is well known that any form of organizational change is difficult (French & Bell, 1995), since employees have established ways of doing things; put differently, any change requires that the change agent fight considerable *social inertia* (Hackman, 1992). A second reason this is difficult is due to the reciprocal relation between an organization's safety climate and its safety record. More specifically, even though many studies have found evidence suggesting that safety climate has a causal impact on accident/injury rates (e.g., Griffin & Neal, 2000), there is equally compelling evidence that the direction of causality runs in the other direction as well (Beus et al., 2010); that is, a high accident/injury rate may lead to the perception of a negative safety climate. This not only makes intuitive sense, but is also consistent with social psychological theory and research suggesting that people often make retrospective explanations of their behavior (e.g., Bem, 1972). In reality, there is probably a complex causal interaction between an organization's actual safety record and its safety climate that plays out over time; unfortunately, empirically capturing this complex interaction would be very difficult, so there is little evidence to document it.

Despite the considerable value in improving an organization's safety record by changing the safety climate, there are very few empirical studies evaluating this type of intervention. One exception was a comprehensive study by Zohar (2003a) that was aimed at changing safety climate by changing the supervisory practices in three organizations. The primary intervention in these

organizations was providing supervisors with feedback regarding their safety-related interactions with their subordinates. In all three organizations, this intervention increased safety-related interactions among supervisors and improved safety climate. In addition, and perhaps most important, the safety-related behavior of employees increased.

Other than this study, few empirical studies have evaluated interventions designed to improve safety climate. DeJoy (2005), however, points out that the accumulated evidence linking safety climate and organizational safety performance suggests that this type of intervention could be quite effective. This conclusion obviously must be tempered by the fact that most studies linking safety climate and safety performance are cross-sectional. Nevertheless, in future research it would be useful to evaluate the impact of interventions designed to change an organization's safety climate both in terms of changes in safety climate itself, and most importantly whether such interventions have a positive impact on the actual safety behavior of employees and their safety performance.

At-Risk Groups

At this point in the chapter, we have discussed a number of workplace health and safety hazards, and have done so in a way that suggests that *all employees* are equally vulnerable to these hazards. We know, however, that this is not the case. In fact, several populations of workers are at increased risk for occupational injury or illness due to a number of individual factors, their employment status, or simply the hazardous nature of their occupation. In this section we discuss a number of at-risk groups, including older workers, contingent workers, minority workers, youth employees, and those in hazardous occupations.

Older Workers

The proportion of workers who are over 55 years in age is expected to increase over the next decade, and more time will be spent working due to increased longevity, reduced retirement benefits, and postponing retirement (Grosch & Pransky, 2009). It has been shown that physical ability declines with age, which will impact performance and injury in the workplace (Van den Berg, Elders, de Zwart, & Burdorf, 2009). Cognitive functions also tend to decline with increasing age. How these changes may affect job performance or injuries for older workers is not clear, nor is it evident what might be stressors for older workers, or how work organization may impact these individuals (Bohle, Pitts, & Quinlan, 2010). Older

workers are more likely to be in nontraditional, contingent work such as being self-employed, or working part time or from home, or as contractors, which may provide more flexibility in terms of meeting work demands (Bohle et al., 2010; Grosch & Pransky, 2009). Older workers typically have higher levels of job satisfaction than their younger counterparts, but are vulnerable when it comes to being downsized or displaced from their employment. Older workers do not tolerate shiftwork well, and may be more likely to have health problems inherent to shiftwork such as gastrointestinal, cardiovascular, and poorer mental health. Older workers may experience "job lock," where they stay in their jobs because of financial need or to maintain health care benefits (Grosch & Pransky, 2009). Older workers may also experience discrimination in the workplace in the form of "ageism" (Powell, 2010). This discrimination involves older workers being stereotyped, bullied, forced to retire, or laid off (Powell, 2010).

There have been very few longitudinal studies of the aging workforce, making it difficult to adequately assess risk factors and outcomes for older workers. Interventions that have been recommended for older workers include those targeting physical demands, psychological demands, and characteristics of the work environment, in addition to those focusing on the worker, the health care system, and the benefits system (Grosch & Pransky, 2009). Future research is needed to address the needs of the aging workforce.

Contingent or Precarious Employment

Contingent workers are those who are employed on a non-permanent basis or in work arrangements outside of the norm (Quinlan, Mayhew, & Bohle, 2001). There has been a growth in working shifts/nights, telecommuting, self-employment, home-based work, part-time work, multiple jobs, outsourcing, and temporary or casual employment. Precarious employment has implications for occupational safety and health. Temporary workers may feel coerced into accepting high-risk jobs, and may also be less experienced on the job and less skilled at worker-to-worker communication (Quinlan et al., 2001). Also, multiemployer worksites (e.g., subcontractors) may have more fragmented work procedures and processes, more complicated management, and contingent workers are not as likely to be included in the decision-making process.

Most occupational safety and health (OSH) programs and policies were not developed with precarious employment in mind. Contingent workers may also be subject to "hoteling" or "hot desking," where two or more employees share the same workspace, which can lead

to competing or conflicting demands and also to musculoskeletal complaints due to the need to adjust equipment to meet the needs of several workers (Quinlan et al., 2001). Precarious employment, while potentially flexible, can also make it difficult to balance work and family life, especially for those who are based at home, but also for those who have unusual work schedules or who work excessive numbers of hours (e.g., self-employed truck drivers). Precarious employment may also be associated with increased risk of occupational violence and harassment; an example of this is home health care workers (Quinlan & Bohle, 2008). Precarious employment also tends to result in underreporting of occupation-related problems, which can affect not only the individual contingent worker, but other workers as well. There have been very few intervention studies involving contingent workers.

Minority Workers

Minority workers make up a large proportion of the U.S. workforce and this proportion is expected to increase (James & Koo, 1991). Much of the research on minority workers has focused on immigrant workers (de Castro, Gee, & Takeuchi, 2008a). This population is very different from those who were native-born, and their job status may be heavily influenced by documentation status and language. Immigrant workers often are subjected to more hazardous duties, longer working hours, lack of safety equipment and training, racial and ethnic discrimination, and lower wages in comparison to non-immigrants. In professional-level jobs, Filipino employees, for example, reported racism, a lack of mentors and opportunities, and management insensitivity (de Castro, Gee, & Takeuchi, 2008b). Racial discrimination is a significant source of job stress that has been linked to increased substance use, depression, cardiovascular disease, and other health problems in several different immigrant and minority populations. Adapting to the new host country can also be a source of stress, and acculturation has been associated with anxiety, distress, and depression. This pattern of job stress impacting health conditions is most pronounced for new immigrants. Immigrant workers are also prone to higher levels of work–family strain, which has been linked to anxiety and depression in both immigrant men and women (Grzywacz et al., 2009). Another stressor facing highly skilled immigrants is that of being under- or unemployed in the host country, where the loss of job-related skills and social status are detrimental to mental and physical health (Dean & Wilson, 2009).

Youth Employees

Young workers in the United States typically enter the workforce at age 15 or 16, but the categorization generally applies to workers who are 15 to 24 years old. By the time they graduate from high school, about 80% of teens will have jobs (Linker, Miller, Freeman, & Burbacher, 2005). There is a growing literature documenting workplace injuries and deaths in adolescents (Linker et al., 2005). Younger workers are often overrepresented in certain industries, including food, retail, hospitality, and service (Breslin, Morasaei, Wood, & Mustard, 2011). These jobs typically involve manual labor that is physically demanding and that requires a low skill level. Despite legislation, young workers often perform dangerous tasks such as working with hot liquids, lifting heavy objects, using tools and equipment, and using chemicals (Vladutiu, Rauscher, Runyon, Schulman, & Villaveces, 2010). Younger workers have a greater likelihood of occupational injuries due to exposure to these hazards, being overloaded in terms of job demands, and from a lack of safety training (Breslin et al., 2011; Vladutiu et al., 2010). Young workers also may perform tasks outside of their normal assignments without training, may be unaware of their rights, experience rapid physical growth, which may make them more vulnerable to injury, and may lack communication skills or the confidence to talk with their supervisors (Linker et al., 2005). When safety training is provided, the nature and effectiveness of the training is often unclear (Breslin et al., 2011). Other risk factors for injury among young workers is a lack of perception of danger or of being vulnerable, sense of powerlessness, and fear of losing their jobs (Linker et al., 2005).

Younger workers may also be at increased risk for workplace bullying and violence due to their overemployment in service, food, and retail sectors (Tucker & Loughlin, 2006). BLS data indicate that young workers aged 15 to 24 years accounted for 18% of the victims of nonfatal work-related assaults and acts of violence (Tucker & Loughlin, 2006). Young workers in the retail trades experience high rates of homicide. Young workers in the service industry report high rates of workplace customer aggression, including verbal and emotional abuse, and sexual harassment. Young females are more likely to be the victims of sexual harassment and mobbing, although males are not as likely to report incidents of workplace aggression. The culture of “the customer is always right” may increase young workers’ risk of being victimized due to the perception that they cannot tell the customer to stop the behaviors (Tucker & Loughlin, 2006).

Current interventions to prevent occupational injury and violence and aggression to young workers center around safety education for teens encompassing work-related issues such as labor laws, workplace hazards, hazard recognition training, communicating effectively, and conflict resolution training (Breslin et al., 2011; Linker et al., 2005; Vladutiu et al., 2010). The effectiveness of these interventions has not been evaluated adequately.

Hazardous Occupations

While those in many occupations experience health and safety hazards, research has shown that firefighters, law enforcement, and emergency services (EMS) are all particularly at increased risk for occupational injuries. While those employed in these occupations experience job stressors that are also experienced by the general public, they are also exposed to unique stressors. These occupations all share common stressors such as dangerous working conditions, possible exposure to workplace violence, high levels of interaction with the public, shiftwork, long hours of work, exposure to traumatic events, the critical nature of their job functions, and long periods of inactivity and then the sudden need to act immediately.

Firefighters and EMS personnel may be exposed to environmental hazards, biological agents, physical stress (e.g., heat), deaths, violence, and mass casualty events. Both groups experience higher rates of musculoskeletal injuries due to the physical nature of the job and the unpredictability of their work environment, and EMS may be also be exposed to vehicle-related risks due to attempting to work in a moving vehicle while also handling patients. Firefighters exposed to these stressors over long periods of time may experience emotional exhaustion, job burnout, and disengagement from the public they are supposed to be serving (Lourel, Abdellaouri, Chevaleyre, Paltrier, & Gana, 2008). Firefighters and EMS are also more likely to experience symptoms of PTSD than the general civilian population in response to exposure to disaster or mass casualty events. Critical Incident Stress Debriefing (CISD) may be used as an intervention despite conflicting evidence as to its effectiveness (Gist & Taylor, 2008). Other interventions include the use of informal peer discussion groups, training on biological and other hazards, health promotion programs, and conflict resolution or deescalation techniques.

Police officers may experience some of these same stressors, but also have their own set of stressors. They, too, experience physical stress on the job and may be at increased risk for cardiovascular disease (Franke et al.,

2010). Likewise police officers may be exposed to biological or chemical agents, mass casualties, and may be the targets of violence while performing their duties. Police officers may be exposed to crime scenes on a regular basis, and may witness fellow officers being killed on the job. The difference here is that the public perception of the police tends to be negative (unlike that of firefighters), which can be a source of stress, and also that police officers are expected to fill many roles in performing their job.

Another class of law enforcement personnel is correctional officers (COs) who work in the local jails and state penal facilities. COs are considered low-level law enforcement jobs, despite the crucial nature of their work (i.e., guarding prisoners). As with other law enforcement personnel, the public perception of COs is negative. COs are also exposed to disease and biological agents in the prisons. The prison system is also burdened by overcrowding, while CO positions remain understaffed. COs are constantly subject to inmate contact and manipulative or aggressive behaviors. Prisons have a backdrop of inmate violence and aggression, and COs must cope with this on a daily basis without being certain that they will receive backup assistance from other COs. Another source of stress for COs is role conflict and ambiguity. COs have one role in which they are to guard inmates and prevent them from escaping or from engaging in violent acts, and another role in which they are supposed to be helping inmates rehabilitate. The level of support from prison management is also likely to be low. COs have a high rate of cardiovascular disease, and die at disproportionately younger ages than similarly matched law enforcement officers working in other arenas. Current research on correction officer stress is focusing on interventions such as developing stress management materials specifically for COs, as well as investigating the work organization and other risk factors for cardiovascular disease in COs.

Interventions for Improving Employee Health

In the earlier section on employee safety, we discussed a number of interventions designed to positively impact safety behavior and attitudes. It is also the case that interventions have been designed specifically to improve employee health. Some of these interventions are designed to remove or otherwise reduce working conditions that are potentially hazardous to employee health; these interventions would be considered a form of primary prevention (Tetrick & Quick, 2011). In other cases, interventions are focused on those who are either at risk for exposure

to adverse health conditions or who have already been negatively impacted; these are referred to as secondary and tertiary interventions, respectively (Tetrick & Quick, 2011). In this sector we focus on primary and secondary interventions.

Healthy Work Organizations

Organizations used to define their wellness or health-based status on their financial or fiscal fitness (Shanbhag, 2010). More recently organizations have noted that employee well-being and satisfaction are also important factors in terms of organizational health. A healthy workplace is one in which everyone in the workplace collaboratively works to promote the health, safety, and well-being of all workers. Healthy workplaces take into account the physical work environment, psychosocial work environment, personal health, and community involvement in improving the health and well-being of not just workers, but also their families and members of the community (Wilson et al., 2004).

Wellness Programs

Workplace wellness or workplace health promotions (WHP) programs have been shown to reduce costs to organizations in terms of reduced health claims, patient costs, life insurance costs, and absenteeism (Mearns, Hope, Ford, & Tetrick, 2010). The idea behind health promotions is the minimization of harmful aspects of the job and the increase of factors that support health (Aust & Ducki, 2004). Enhancing employee well-being through health promotions programs is most beneficial when employees are involved in the decision-making process and are empowered. This investment in workplace health may involve disseminating health information to employees through many methods, providing training courses (e.g., stress management, safe lifting, safe equipment use, etc.), and providing fitness facilities and health screening programs (Mearns et al., 2010). Ideally, health promotion programs reflect a genuine interest on the part of the organization in maintaining the well-being of its employees. It is hoped that healthy employees who feel that their organization cares about them will perform better as well. Mearns et al., (2010) noted a relationship between health promotions and investment practices and workplace safety and health climate, as well as increased organizational commitment from employees.

Health Circles

Health circles are discussion groups in the workplace that are formed for the purpose of improving working

conditions, with an emphasis on psychosocial factors and stress (Aust & Ducki, 2004). Health circles involve employees in decision making, and, since they encourage other viewpoints, may increase coworker and supervisor support and provide a stable social network for employees. Looking at health data such as absenteeism, sick leave, and health insurance, different departments may construct an idea about the relationship between working conditions and these health outcomes, and this may be followed by employee surveys about the physical and psychosocial demands of work. These analyses are the starting point for the health circle discussion. In a series of studies in Germany, many companies implemented health circle suggestions (Aust & Ducki, 2004), and many studies indicated improvements in the work organization and in communication. Studies have also shown improved psychological and physical well-being and increased work satisfaction among health circle participants (Aust & Ducki, 2004). There are still relatively few evaluation studies of health circles and their effect on employee well-being.

Workplace Violence Prevention

Workplace violence is a serious occupational hazard. The definition of workplace violence may encompass a wide set of physical and nonphysical behaviors intended to harm those in the workplace. Bureau of Justice Statistics (BJS) data indicate that approximately 1.7 million workers are the victims of physical assaults in the course of performing their jobs, and homicide on the job is the fourth leading cause of death while on the job (BJS, 2001). Occupations most strongly affected by workplace violence are law enforcement, retail trade, health care and social assistance, and the service industry.

There are several risk factors associated with workplace violence, including exchanging money, contact with the public, transporting passengers, delivering goods, working at night, working alone or with only a few other employees, and working with potentially violent, unstable, or mentally ill individuals (NIOSH, 2006). General workplace violence prevention programs may contain written organizational policies, multidisciplinary response and threat assessment teams, and training for employees specifically on workplace violence (NIOSH, 2006).

More specific strategies can be classified as environmental, administrative, or behavior interventions. Environmental designs (CPED—Crime Prevention through Environmental Design) aimed at preventing workplace violence include cash control techniques, cash handling procedures (e.g., drop safes, signage indicating that there are small amounts of cash at an establishment), physical

separation of the worker from customers/clients/patients (e.g., barriers, bullet-resistant partitions or enclosures; increased height and depth of counters separating worker from customer), increased visibility and lighting, controlled entry and exit, surveillance cameras, keycard access systems, trouble lights, personal protective equipment (e.g., ballistic vest), and geographic locating systems for mobile personnel (e.g., law enforcement officers, taxi drivers, social workers, etc.).

Administrative interventions include adequate staffing, work practices such as escorting visitors or clients/patients, security personnel and screening, opening and closing procedures for establishment, money drop and pickup procedures, restricted hours of operation, and policies and procedures for assessing and reporting threats (NIOSH, 2006).

Behavioral strategies include employee training on risk awareness, communication and interpersonal relations, how to deal with potentially aggressive people, conflict resolution, de-escalation techniques, and appropriate take-down and restraint methods for police and other law enforcement officers (NIOSH, 2006).

Secondary and tertiary interventions for the aftermath of violence may include psychological first aid (PFA), critical incident stress debriefing (CISD), employee assistance programs (EAP), human resources (HR), occupational health and wellness services (OHS), and community mental health services.

Intervention effectiveness evaluations indicate that environmental designs in retail establishments can be effective deterrents to robbery and violent acts, particularly if multiple environmental designs are utilized (Wassell, 2009). Most of the environmental methods mentioned above have demonstrated a reduction in workplace violence. The issue is one of compliance. Some organizations or businesses will not implement preventive strategies due to the financial cost or because they do not see the importance of the measures, and this is particularly the case for small businesses (Peek-Asa, Casteel, Mineschian, & Erickson, 2004). In this context there has been little effect on the injury and homicide rates because of this failure to accept or to implement preventive methods. More research on barriers to implementing environmental designs is needed, particularly for small, independently owned retail businesses.

Other efforts at workplace violence interventions have been in the health care sector. The dynamic is very different from that of retail, as it involves the interface of a health care provider with a patient, and the patient is likely to be the one who engages in violent behavior. Thus

far, there has been little evidence that training in managing potentially violent patients has been effective in terms of reducing injuries to health care staff (Wassell, 2009). It is not clear from the literature which training components are useful or effective for reducing workplace violence in this setting, and more evaluation studies and standardized procedures are needed in the future.

Conclusions and Recommendations

The purpose of this chapter was to provide a reasonably comprehensive review of occupational health and safety that was aimed at psychologists. Traditionally this has not been a major area of study within psychology, but with the recent development and expansion of the field of Occupational Health Psychology that has changed. Given the intended audience for this chapter, we covered either topics that are heavily studied by psychologists (e.g., workplace violence, occupational stress) or those where psychologists may have important contributions to make (e.g., ergonomics, safety, job insecurity).

The fact that the chapter is aimed at psychologists is important because many issues in occupational health and safety are either impacted by psychological issues, or have psychological ramifications within organizations. With that being said, readers should also recognize that a psychologist's view of occupational health and safety is certainly not without limitations. For example, other than the section on safety, we devote relatively little coverage in this chapter to physical hazards in the workplace, despite the fact that these are likely to be the most important factor impacting the health and safety of many employees. We point this out to the reader simply to make the point that even though psychologists bring an important perspective to the study, it is after all one of *many* perspectives. An industrial hygienist could very well have written this chapter and it would have looked very different from the current chapter; nevertheless, his or her insights would have been no less valuable than what we have covered here.

What, then, can be concluded about occupational health and safety that is relevant to psychologists? The first conclusion, and one that follows from what was presented above, is that health and safety in organizations are impacted by a number of factors, of both a physical and psychological nature. Furthermore, in many cases health and safety are impacted by complex interactions between psychological and physical factors. Probably the best example of this described in the present chapter is recent work examining the interaction between job

insecurity and safety (Probst, 2004), but there are undoubtedly other ways that the physical and psychosocial work environments interact. Thus, when we try to understand why an employee is “unhealthy” or “unsafe” we must go beyond the boundaries of our own discipline.

A second conclusion is that creating healthy work organizations is about more than just decreasing accident rates and lowering health care costs. While such goals are certainly important in the short-term, they are also limited in that they typically address only *known* hazards in the physical and psychological work environment. In order to truly impact the health, safety, and overall well-being of employees in organizations what is really needed is a fundamental change in the culture of many organizations. With respect to health, more than 15 years ago researchers at NIOSH described the characteristics of healthy work organizations (e.g., Sauter, Lim, & Murphy, 1996); yet, to date there has been relatively little research on this important concept. In the area of safety there has been a great deal of research on “safety climate” (e.g., Clarke, 2006), and more specifically the dimension of safety climate that has been termed *safety participation*. Safety participation occurs when employees go beyond compliance with current safety regulations and take proactive steps to improve safety within organizations (Griffin & Neal, 2000). Furthermore, there is evidence that safety participation is impacted by the leadership within an organization (Barling et al., 2002) and that it does impact “bottom line” safety indices (Christian et al., 2009). The broader implication of this, in our opinion, is that health and safety within organizations are strongly impacted by the extent to which these things *matter* within organizations. Furthermore, improving health and safety within an organization is just as much about changing the culture and mindset within an organization as it is about providing safety training or health promotion.

A third conclusion one can draw is that despite the fact that this chapter is focused on healthy workplaces, the majority of research we’ve reviewed is designed to predict “illness” and “accidents.” More specifically, most of the psychologically based research in occupational health and safety has a negative focus. To a certain extent, this makes logical sense given the nature of the variables that many occupational health and safety researchers include in their research (e.g., workplace violence, work–family conflict, role ambiguity, etc.). However, it also raises an important question: Does the absence of a known hazard in the work environment necessarily promote the health and safety of employees? For example, does a low level of interpersonal conflict equate with “interpersonal harmony”? Does a low

level of work–family conflict mean that work and family domains are highly compatible?

Attempting to answer such questions is obviously beyond the scope of the chapter, but recent research in the domain of positive psychology suggests that the answer to both of these questions may in fact be “No” (e.g., Britt, Dickinson, Moore, Castro, & Adler, 2007). Thus, when we find that interpersonal conflict is positively correlated with psychosomatic symptoms (Spector & Jex, 1998), this does not necessarily mean that decreasing interpersonal conflict will enhance overall physical health. Thus, more research on predictors of positive physical and psychological states is clearly needed. For example, recent work on employee engagement (e.g., Albrecht, 2010) suggests that this may be a promising predictor of both positive physical and psychological states.

A fourth and final conclusion is that there is a great need for intervention studies. For the majority of topics covered in this chapter, there were far more studies investigating predictors of occupational safety and health problems compared to studies investigating the impact of interventions designed to bring about positive health and safety outcomes in organizations. Furthermore, interventions should have a firm basis in psychological theory and research. We believe that for most topics in occupational health and safety we certainly know *enough* to form the basis for sound interventions.

In conclusion, we hope that we have conveyed to readers both the scope and importance of the field of occupational health and safety. This is an area where psychologists are well equipped to contribute to theory, research, and the design of interventions. If the primary goal of psychology is to “promote human welfare,” and we believe that it is, there are few areas of human functioning where psychologists can have a greater impact in promoting this goal than by helping to insure that employees work in a healthy and safe environment.

Organizational culture and climate focus on how organizational participants observe, experience, and make sense of their work environment (Schneider, Ehrhart & Macey, 2011a) and are fundamental building blocks for describing and analyzing organizational phenomena (Schein, 2000). Although culture and climate have been approached from different scholarly traditions and have their roots in different disciplines, they are both about understanding psychological phenomena in organizations. Both concepts rest upon the assumption of shared meanings—a shared understanding of some aspect of the organizational context.

Historically, the construct of climate preceded the construct of culture. The social context of the work environment, termed “atmosphere,” was discussed as early as 1910 (Hollingworth & Poffenberger, 1917; Münsterberg, 1915; Scott, 1911), and was among one of the many topics investigated at the National Institute of Industrial Psychology (NIIP) during the 1930s in Britain (Kwaitkowski, Duncan, & Shimmin, 2006). Climate was formally introduced in the 1960s, primarily based on the theoretical concepts proposed by Kurt Lewin (Lewin, 1951; Lewin, Lippitt, & White, 1939) and followed by empirical research (e.g., Litwin & Stringer; 1968; Stern, 1970). Organizations were examined from a cultural perspective as early as the 1930s (Trice & Beyer, 1993); however, organizational culture did not become a popular issue for study in the management literature until the 1980s, largely following the publication of several best-selling trade books.

A great deal of attention has been devoted to the question of whether the constructs of culture and climate are different, the same, or interrelated, primarily highlighting the similarities and differences between them (see Denison, 1996; Payne, 2000; Schein, 2000). Recently, scholars have taken this a step further, focusing on how and why the two constructs can be linked to provide a more comprehensive and parsimonious view of the higher order social structure of an organization (Schneider, Ehrhart, & Macey, 2011b; Zohar & Hofmann, in press). Along those lines, we view culture and climate as two complementary constructs that reveal overlapping yet distinguishable nuances in the psychological life of organizations (Schneider, 2000). Each is deserving of attention as a separate construct as well as attention to the relationship between the two constructs. Further, the continued study of culture and climate is important because these constructs provide a context for studying organizational behavior. That is, the social and symbolic processes associated with organizational culture and climate influence both individual and group behaviors, including turnover, job satisfaction, job performance, citizenship, safety, customer satisfaction, service quality, and organizational-level indicators of effectiveness (Schneider et al., 2011a). We structure this chapter by providing separate reviews and discussion of the culture and climate literature before turning to the relationships between the two constructs and the processes underlying their emergence, strength, and change.

INTEGRATED MODEL OF CULTURE AND CLIMATE

Before providing an overview of our integrated model shown in Figure 24.1, it is important to define the constructs of culture and climate. Climate is an experientially-based description of what people “see” and report happening to them in an organizational situation (L. R. James & Jones, 1974; Schneider, 2000). Climate involves employees’ perceptions of what the organization is like in terms of practices, policies, procedures, routines, and rewards (e.g., A. P. Jones & James, 1979; Rentsch, 1990; Schneider et al., 2011b). Hence, climate’s focus is on the “situation” and its link to perceptions, feelings, and behavior of employees. It can be viewed as temporal, subjective, and possibly subject to manipulation by authority figures (Denison, 1996).

While climate is about experiential descriptions or perceptions of *what* happens, culture helps define *why* these things happen (Schein, 2000; Schneider, 2000). Culture pertains to fundamental ideologies (Trice & Beyer, 1993) and assumptions (Schein, 2010) and is influenced by symbolic interpretations of organizational events and artifacts (Hatch, 2011). Culture represents an evolved context embedded in systems, is more stable than climate, has strong roots in history, is collectively held, and is resistant to manipulation (Denison, 1996; Schein, 2010). Some empirical support has been offered to demonstrate that culture and climate are distinct constructs (e.g., Glisson & James, 2002; Rentsch, 1990).

Thus, climate is more “immediate” than culture. Individuals can sense the climate upon entering an organization through things such as the physical look of the place, the emotionality and attitudes exhibited by employees, and the experiences and treatment of visitors and new employee members (Schneider et al., 2011b). Climate resides within individuals in their perceptions of the organizational context, and when these perceptions are shared across individuals, the higher-level social construct emerges (L. R. James et al., 2008). In contrast, culture is a property of the collective (Martin, 2002), reflecting deeper phenomena based on symbolic meanings (Hatch, 2011), and shared meaning about core values, beliefs, and underlying ideologies and assumptions (Schein, 2010; Trice & Beyer, 1993). Organizations and work units thus are the appropriate level of analysis in culture research (Glisson & James, 2002).¹ The interpretative or sense making process

individuals engage in to understand culture explains the “why” of organizational behavior. Climate develops from the deeper core of culture. Climate, or “what,” can result from espoused values and shared tacit assumptions and reflects the surface organizational experience based on policies, practices, and procedures (Guion, 1973; Schein, 2000). As such, their integration can be accomplished by viewing climate as the lens through which the deep layers of culture can be understood (Zohar & Hofmann, in press).

Figure 24.1 represents a heuristic model for locating culture and climate in a conceptual framework across aggregate and individual levels of analysis and is used to help structure our review. When we developed the framework in the 2003 version of the *Handbook*, relatively few of the linkages had been tested, but this situation has changed dramatically, highlighting the key role that culture and climate play in understanding organizational phenomena.

Figure 24.1 shows that organizational culture is a function of industry and environmental characteristics, national culture, founder’s values, and an organization’s vision, goals, and strategy (Aycan, Kanungo, & Sinha, 1999). While recent work has shown that most of the variance in organizational culture is not explained by country differences or by differences in national cultures (Gerhart, 2008), the relationship between societal/national culture and organizational culture may be more complex than depicted in our multilevel model (Brodbeck, Hanges, Dickson, Gupta, & Dorfman, 2004; Dickson, BeShears, & Gupta, 2004).

Returning to Figure 24.1, organizational culture is expected to align with and relate to structure, practices, policies, and routines in the organization that in turn provide the context for climate perceptions. Some research has demonstrated relationships between culture and practices (e.g., Chow & Liu, 2009; Chow & Shan, 2009), although directionality has not been established. Organizational practices are the means through which employees’ perceptions of climate and subsequent attitudes, responses, and behaviors are shaped. At the unit or organizational level, cultural values and assumptions lead managers to the explicit or implicit adoption of structural features and practices that influence the climate that develops. Leaders are purported to play a key role not only in creating and shaping the culture and climate (Schein, 2010; Schneider et al., 2011b) but also in facilitating appropriate alignment between culture, practices, and climate (Chow & Liu, 2009). Collective attitudes and behaviors of employees are shaped by climate and in turn impact organizational effectiveness, performance, and efficiency. Support for the

¹We define work units as a collection of individuals that include, but are not limited to, strategic business units, divisions, departments, and teams within organizations.

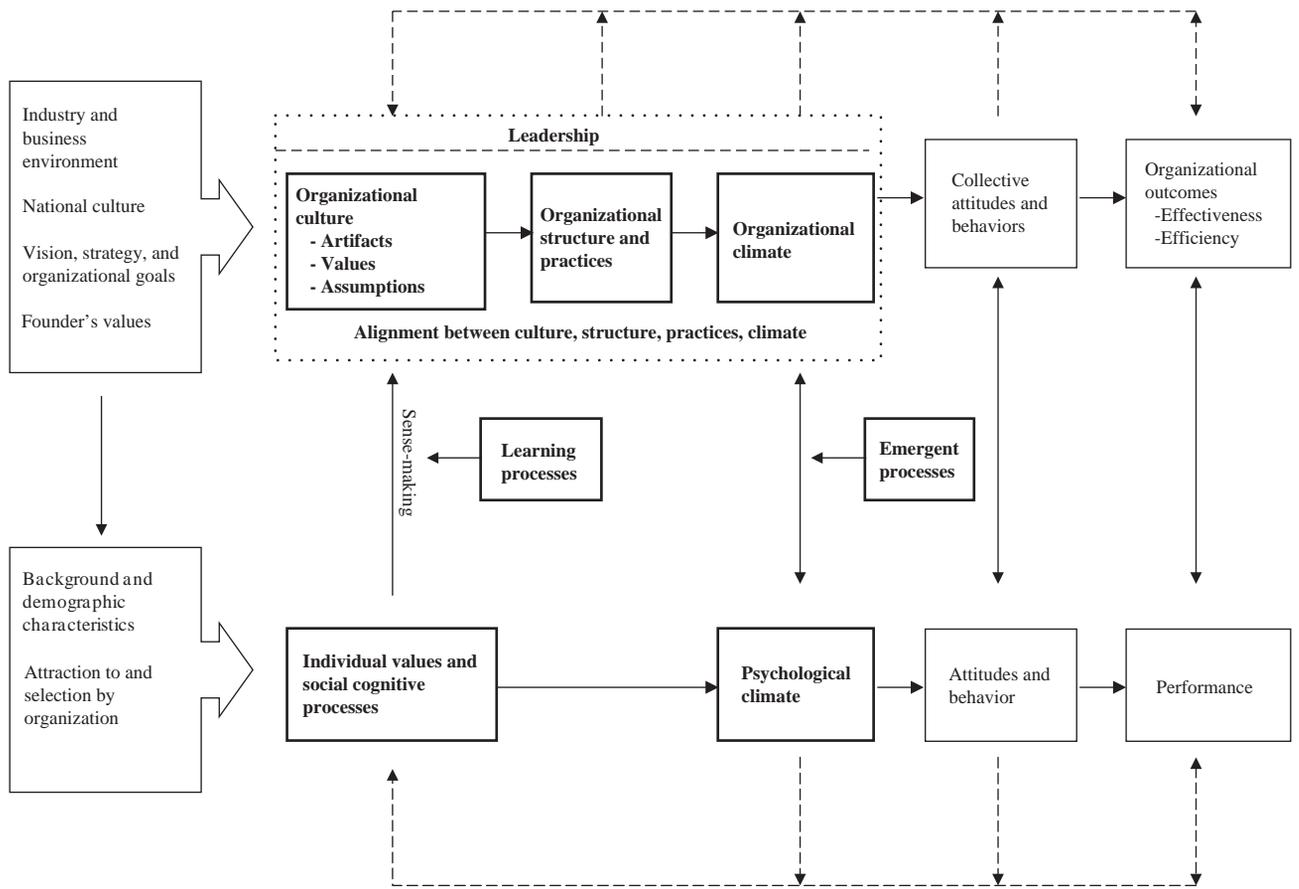

Figure 24.1 Multilevel model of organizational culture and climate

linkages has been demonstrated in several recent studies (e.g., Hemmelgarn, Glisson, & James, 2006; Ngo, Foley, & Loi, 2009; Rogg, Schmidt, Shull, & Schmitt, 2001).

Culture is learned over time. It is a product of vicarious and experiential learning (Bandura, 1977; Schein, 2010) that results from myriad interactions between leaders and unit members and produces sense making (Hartnell & Kinicki, 2011). Figure 24.1 further shows that individuals' background characteristics and process of joining the organization are related to individuals' values and social cognitive processes, which in turn influence psychological climate (L. A. James & James, 1989). When these climate perceptions are shared across an organization's employees, unit or organizational climate is said to emerge (L. R. James & Jones, 1974). We also propose that these shared perceptions will develop only when strong emergent processes are enacted in the organization (practices delivered in such a way as to create a strong situation, homogeneity of attributes among employees, interactions with other processes, social tuning to adjust perceptions to others, group processes, and leadership). When the emergent process is weak, idiosyncratic perceptions within an organization develop, producing wide variability in perceptions of climate, which can result in wide variability in individual attitudes and behaviors, diminishing the relationship to organizational performance (Ostroff & Bowen, 2000).

Finally, reciprocal relationships between the variables across the aggregate and individual level are proposed. Individual-level constructs are influenced in part by the existing organizational-level constructs; for example, individual climate perceptions are influenced by the existing organizational climate; individual attitudes and behaviors are influenced in part by the collective attitudes and behaviors. At the same time, individual constructs have a role in creating the contextual variables (Kozlowski & Klein, 2000). Finally, we include feedback loops at both levels of analysis. It is important to note the model is not comprehensive and we did not include all possible linkages, variables, and moderators in Figure 24.1. Rather, our purpose was to highlight those relationships that are most critical for integrating culture and climate across levels of analysis; boxes in bold represent the constructs and linkages that are our primary focus.

ORGANIZATIONAL CULTURE

This section begins by providing a historical overall review of the construct of organizational culture. We then

consider the layers of organizational culture, the content or types of organizational cultures, and the antecedents and outcomes of organizational culture.

Historical Foundation and Definition of Organizational Culture

Research on organizational culture has its roots in anthropology. This research relies heavily on qualitative methods that use participant observation, interviews, and examination of historical information to understand how culture provides a context for understanding individual, group, and societal behavior. The application of participant observation and employee interviews to understand employee attitudes, behavior, and performance dates back to the 1930s. This work was followed by Gardner's textbook (1945) that examined organizations from a cultural perspective. Interest in an anthropological approach to studying work organizations nonetheless waned from the 1940s through early 1960s. While there was a resurgence in anthropologically based studies in the 1960s (e.g., Trice, Belasco, & Alutto, 1969) and 1970s (e.g., Mintzberg, 1973), the topic of organizational culture did not become prominent until the 1980s.

This interest in organizational culture was stirred by anecdotal evidence contained in three best-selling books: Ouchi's (1981) *Theory Z: How American Business Can Meet the Japanese Challenge*; Deal and Kennedy's (1982) *Corporate Cultures: The Rites and Rituals of Corporate Life*; and Peters and Waterman's (1982) *In Search of Excellence*. Each suggested that strong organizational cultures were associated with organizational effectiveness. The number of applied and scholarly publications on the topic of organizational culture has mushroomed since the 1980s (Hartnell, Ou, & Kinicki, 2011; Sackman, 2011) and is likely to continue in light of findings suggesting that organizational culture is one of the biggest barriers to creating and leveraging knowledge assets (De Long & Fahey, 2000), to effectively implementing total quality management programs (Tata & Prasad, 1998), and to successfully implementing technological innovations (DeLisi, 1990).

The concept of organizational culture has a variety of meanings and connotations. For example, Verbeke, Volgering, and Hessels (1998) identified 54 different definitions in the literature between 1960 and 1993. Part of this inconsistency is due to the fact that culture researchers represent an eclectic group that come from a variety of disciplines (such as sociology, anthropology, and psychology) and use different epistemologies and methods to investigate organizational culture. That said,

Hofstede, Neuijen, Ohayv, and Sanders (1990) conclude that there are some common characteristics across the different definitions of organizational culture. These commonalities include the notion that organizational culture includes multiple layers (Schein, 2010) and aspects (i.e., cognitive and symbolic) of the context (Mohan, 1993), that organizational culture is a socially constructed phenomenon influenced by historical and spatial boundaries (Schein, 2000; Schneider et al., 2011b), and the concept of “shared” meaning that is central to understanding an organization’s culture.

While a variety of definitions of culture that integrate these commonalities have been offered, the most comprehensive one has been offered by Schein (2010):

a pattern of shared basic assumptions learned by a group as it solved its problems of external adaptation and internal integration, which has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems. (p. 18)

Schein suggests that organizational culture is learned by unit members who pass it on to new members through a variety of socialization and communication processes. This definition also implies that overt behavior, while not directly part of organizational culture, is clearly influenced by the basic assumptions or ideologies (Trice & Beyer, 1993) people hold.

Martin (1992, 2002) proposed that organizational culture can be considered from integrative, differentiated, or fragmented perspectives. An integrative perspective is based on the idea that organizations have one overriding or *gestalt* culture, an idea that is still being debated in the literature (Harris & Ogbonna, 1999; Hartnell & Walumbwa, 2011). It is important to note that the existence of an overriding culture does not negate the existence of multiple components or dimensions. For example, Southwest Airlines’ *gestalt* culture includes beliefs, values, and assumptions related to being employee-centric, customer focused, and productive. Most research to date has adopted an integrative viewpoint. The differentiated perspective accepts the premise that organizations have numerous subcultures. Subcultures represent a focal unit’s (e.g., group, division, geographic location) shared values, beliefs, norms, and assumptions. Although the notion of subcultures is well accepted, very little research has empirically examined them or considered their relationship with a *gestalt* culture (Li & Jones, 2010). Subcultures are discussed later in this chapter. Finally, Martin (1992, 2002) believes that a fragmented point of view is needed because of the ambiguity

associated with knowing whether or not *gestalt* cultures and subcultures exist. In conclusion, although research has not examined comparative relationships between Martin’s three perspectives and measures of organizational effectiveness, we believe that it underscores the conclusion that organizational culture can be studied at multiple levels or units of analysis (e.g., organizational, departmental, functional, etc.) and from different vantage points (*gestalt* vs. subculture vs. configural system).

Layers of Organizational Culture

Numerous scholars have proposed that organizational culture possesses several layers or levels that vary along a continuum of accessibility and subjectivity (Hofstede et al., 1990; Schein, 2010). Schein (2010) concludes that there are three fundamental layers at which culture manifests itself: observable artifacts, espoused values, and basic underlying assumptions.

Observable Artifacts

Artifacts are surface-level realizations of underlying values that represent manifestations of deeper assumptions (Schein, 2010) or ideologies (Trice & Beyer, 1993). Artifacts include the

visible products of the group, such as the architecture of its physical environment; its language; its technology and products; its artistic creations; its style, as embodied in clothing, manners of address, and emotional displays; its myths and stories told about the organization; its published lists of values; and its observable rituals and ceremonies. (Schein, 2010, p. 23).

Trice and Beyer (1993) conclude that there are four major categories of cultural artifacts: symbols (e.g., natural and manufactured objects, physical settings, and performers and functionaries), organizational language (e.g., jargon and slang, gestures, signals, signs, songs, humor, jokes, gossip, rumor, metaphors, proverbs, and slogans), narratives (e.g., stories, legends, sagas, and myths), and practices (e.g., rituals, taboos, rites, and ceremonies).

Espoused Values

Schwartz (1992) notes that values possess five key components:

Values (1) are concepts or beliefs, (2) pertain to desirable end-states or behaviors, (3) transcend situations, (4) guide selection or evaluation of behavior and events, and (5) are ordered by relative importance. (p. 4).

Espoused values reflect values that are specifically endorsed by management or the organization at large; close to 90% of organizations across numerous countries have written documents stating espoused corporate values (e.g., Van Lee, Fabish, & McGaw, 2002). In contrast, enacted values represent values that are exhibited or converted into employee behavior. Gruys, Stewart, Goodstein, Bing, and Wicks (2008) coined the term *values enactment* to represent the connection between behaving in ways that are consistent with the espoused values, and they studied its antecedents and outcomes at the individual level of analysis. Results revealed that individuals' value enactment was higher when employees had longer tenure and when employees in the unit displayed greater values enactment on average.

Basic Assumptions

Basic assumptions are unobservable and reside at the core of organizational culture (Schein, 1990, 2010). Deeply held assumptions frequently start out as values that over time become so ingrained or taken for granted that they take on the character of assumptions. Basic assumptions are rarely confronted or debated and are extremely difficult to change. Challenging basic assumptions produces anxiety and defensiveness because they provide security through their ability to define what employees should pay attention to, how to react emotionally, and what actions to take in various kinds of situations (Schein, 2010).

Moreover, Trice and Beyer (1993) and Hatch (1993) criticize Schein's proposal that basic assumptions represent the core of culture because assumptions ignore the symbolic nature of culture. Trice and Beyer suggest that ideologies represent the core content or substance of a culture. Ideologies are "shared, relatively coherently inter-related sets of emotionally charged beliefs, values, and norms that bind some people together and help them to make sense of their world" (Trice & Beyer, 1993, p. 33). Hatch also believes that Schein's model is deficient because it fails to consider interactive processes between artifacts, values, and assumptions. We concur with Hatch's evaluation and recommend that future work investigate the dynamic relationships between the layers of culture.

The Content of Organizational Culture

Most researchers either conduct a qualitative analysis to assess the content of organizational culture (e.g., Ford, Wilderom, & Caparella, 2008; Schein, 2010), or use surveys to quantitatively assess espoused values and beliefs

(e.g., Cooke & Szumal, 2000; O'Reilly, Chatman, & Caldwell, 1991) or a set of work practices thought to underlie organizational culture (e.g., Hofstede, 1998; Hofstede et al., 1990). Ashkanasy, Broadfoot, and Falkus (2000) reviewed questionnaire measures of organizational culture and concluded that many are used for consultative purposes, lack a sound theoretical basis, are infrequently used, and lack validity. Hartnell et al.'s (2011) meta-analytic review found 46 of the 94 studies used ad-hoc measures with limited evidence of validity. Further, other researchers (e.g., Schein, 2000; Trice & Beyer, 1993) do not accept the premise that surveys are a valid measure of organizational culture and conclude that they should not be used as the principal method for assessing organizational culture.

We concur with both Martin (2002) and Schneider et al. (2011a) that it is not relevant to argue for the merits of using surveys versus case studies to assess organizational culture. There simply is too much variety in each general method, and they both provide valuable information. The survey-based research has allowed for identifying different taxonomies of organizational culture to examine the content of culture. To that end, there are five culture surveys that are theoretically based and have been subjected to preliminary validation, each of which is discussed briefly below.

The *Organizational Culture Inventory* (OCI; Cooke & Lafferty, 1987) categorizes culture into three types. A constructive culture endorses normative beliefs associated with achievement, self-actualizing, humanistic-encouraging, and affiliative. The second type, a passive-defensive culture, reinforces values related to seeking approval, being conventional or dependent, and avoiding accountability. Finally, an aggressive-defensive culture endorses beliefs characterized as oppositional, power oriented, competitive, and perfectionist. Evidence supporting the reliability and validity of the OCI is provided by Cooke and Szumal (1993) and Cooke and Szumal (2000).

The *Competing Values Framework* (CVF) was developed by Quinn and his associates (Quinn & McGrath, 1985; Quinn & Rohrbaugh, 1983) and produces an assessment of the extent to which an organization possesses four core cultural types: group (now called clan), developmental (now called adhocracy), rational (now called market), and hierarchical (now called hierarchy) (see Cameron, Quinn, Degraff, & Thakor, 2006). These four types are based on the intersection of two axes—structure and focus. The structure axis contrasts flexibility and discretion with stability and control and the focus dimension contrasts an internal versus external orientation. The CVF

is the most frequently used measure of organizational culture (Hartnell et al., 2011) and its four-factor structure was supported in several studies (e.g., McDermott & Stock, 1999; Zammuto & Krakower, 1991); it was found to generalize to companies in Australia (Lamond, 2003), Korea (Choi, Seo, Scott, & Martin, 2010), and Hong Kong (Kwan & Walker, 2004).

Denison and Mishra (1995) developed the *Denison Organizational Culture Survey (DOCS)* by rotating the CVF's dimensional axes pertaining to structure and focus to create their own four culture types. The types have different names than the CVF, but they are essentially the same.

The *Organizational Culture Profile (OCP)* (O'Reilly et al., 1991) measures eight dimensions of culture (innovation, attention to detail, outcome orientation, aggressiveness, supportiveness, emphasis on rewards, team orientation, and decisiveness). The survey was originally based on the Q-sort methodology and has more recently been converted to Likert-type items (e.g., Sarros, Gray, Densten, & Cooper, 2005). Research using the OCP has shown that it possesses interrater reliability, test-retest reliability, within- and between-group differences, and predictive validity. However, factor analysis of the 54 items has identified different factor structures across samples (cf., O'Reilly et al., 1991; Sarros, Gray, Densten, & Cooper, 2005). In an attempt to overcome measurement problems associated with the original OCP, Ashkanasy et al. (2000) developed a 50-item survey to measure 10 dimensions of organizational culture. Unfortunately, validation studies of this instrument uncovered a two-factor solution, thereby failing to support the a-priori dimensionality of this newly proposed instrument.

Hofstede et al. (1990) developed the *Work Practices Survey* to measure organizational culture. Examination of the items, however, indicates that they assess employees' perceptions of general and specific work-environment characteristics. Consistent with our definitions of culture and climate, we believe that these measures are actually tapping climate, not culture, and recommend that they not be used as indicators of organizational culture.

Antecedents of Organizational Culture

Very little research has examined the antecedents of organizational culture. What has been written in this regard is predominantly theoretical and antecedents come from outside or inside the organization. Predicted external antecedents include industry and business environments (Dickson et al., 2004), national culture (Hofstede et al.,

1990), external stakeholders such as local communities, local media outlets, and environmental groups (Hatch, 2011), and external cultures anchored outside the organization such as competitors, strategic alliances, political parties, and professional associations (Harrison & Corley, 2011). Discussion of internal antecedents primarily revolves around the role of leadership and the values, beliefs, and assumptions of employees working in the unit. Schein (2010, p. 219), for example, aptly notes that "cultures basically spring from three sources: (1) the beliefs, values, and assumptions of founders of organizations; (2) the learning experiences of group members as their organization evolves; and (3) new beliefs, values, and assumptions brought in by new members and leaders." There clearly is consensus among researchers and practitioners that the founders of a new organization play a key role in forming culture and that leaders in general exert significant influence in how culture is maintained and changed over time (e.g., Hartnell & Walumbwa, 2011; Jung, Wu, & Chow, 2008; Trice & Beyer, 1993).

The direct effect of leadership on culture has been demonstrated. Berson, Oreg, and Dvir (2008) revealed that CEOs' self-directive values were positively associated with innovative cultures, security values were positively related to bureaucratic cultures, and benevolence values were positively correlated with supportive cultures. Similarly, Giberson, Resick, Dickson, Mitchelson, Randall, and Clark's (2009) results demonstrated that CEO values and personality were associated with the four culture types within the CVF in hypothesized directions.

Outcomes of Culture

Culture has been viewed as a key driver of organizational effectiveness (e.g., Deal & Kennedy, 1982; Peters & Waterman, 1982). The theoretical rationale for this relationship is founded on the resource-based view (RBV). According to the RBV organizations create competitive advantage by creating firm resources that are valuable, rare, inimitable, and nonsubstitutable, and organizational culture can be one of these resources (Barney, 1991). Three qualitative reviews of the relationship between culture and measures of organizational effectiveness were discussed in the 2003 version of this chapter and all three resulted in similar conclusions: There is not a significant relationship between organizational culture and organizational effectiveness. Hartnell et al. (2011) proposed that this conclusion was premature and conducted a meta-analysis of studies published between 1980 and January 2008 to provide a quantitative assessment of relationships

between organizational culture and measures of organizational effectiveness.

In the Hartnell et al. (2011) meta-analysis, measures of culture were coded into the CVF cultural types and measures of organizational effectiveness were coded into categories of employee attitudes, operational effectiveness, and financial effectiveness. Hierarchical cultures were not examined due to a lack of studies using this culture type. Overall, 23 out of 25 positive correlations between culture types and the measures of effectiveness were significant.

Overall, Hartnell et al.'s (2011) results demonstrate that types of organizational culture have differential relationships with criteria (see Boggs & Fields, 2010) and many of these relationships are moderated. Correlations between culture and effectiveness also varied in terms of their strength, suggesting the need to examine additional moderators and mediators of the culture–effectiveness relationship. Finally, the results revealed that the three culture dimensions were moderately to largely correlated with each other. One conclusion derived from this later finding is that culture dimensions interact with each other to further account for culture's role in firm effectiveness, which thereby reinforces the need to examine cultural configurations.

Mediators and Moderators

We uncovered three different theoretically derived patterns of relationships between organizational culture and outcomes. Similar to Figure 24.1, results support the view that organizational culture is a key exogenous variable that indirectly influences outcomes via multilevel mediators such as leadership (Chen, 2004), individual needs (Cardador & Rupp, 2011), human resource practices and policies (Carroll, Dye, & Wagar, 2011), and corporate reputation (Flatt & Kowalczyk, 2008). In contrast, other studies support linkages in which culture serves as a mediator of relationships between corporate responsibility and human resource practices and various outcomes (Surroca, Tribó, & Waddock, 2010). Finally, several studies support the argument that organizational culture is a key social contextual variable that moderates the relationship between leadership and criteria such as organizational commitment (Chen, 2004), innovation (Jung et al., 2008), and employee attitudes and financial effectiveness (Kinicki, Jacobson, Galvin, & Prussia, 2011). Organizational culture also was found to be an inconsistent moderator of the linkage between human resources practices and policies and various criteria (Carroll et al., 2011).

Conclusion

Five key conclusions can be derived from research on the content of organizational culture. First, we concur with Martin (2002) and Schneider et al. (2011a) that it is impossible and illusionary to resolve this paradigmatic argument about whether culture should be measured ethnographically or via surveys. Second, organizational culture can be measured and organizations can be differentiated on the basis of their cultures (cf. Cameron et al., 2006; Fey & Denison, 2003). Third, although the CVF and DOCS have been the most frequently used measures of culture since 1980 (see Hartnell et al., 2011), there may be other valuable dimensions of culture worth investigating. For example, researchers have discussed the importance of considering “strategically oriented” cultures that are customer focused (Ford et al., 2008), innovative (Dombrowski et al., 2007), or ethical (Zhang, Chiu, & Wei, 2009). Fourth, past research is plagued with problems associated with levels of analysis. Specifically, although organizations and work units are the correct level of analysis in culture research, many researchers continue to measure culture by assessing individuals' perceptions of values—similar to measures of psychological climate—and then analyze data at the individual level of analysis (Hartnell et al., 2011). Individual perceptions of culture represent a very different construct than unit or organizational culture, and labeling such studies as *culture* distorts and convolutes knowledge about organizational culture (see Yammarino & Dansereau, 2011) because results based on idiosyncratic perceptions get interpreted as if they apply to unit-level data and analysis (see Sackman, 2011). We encourage both journal editors and reviewers to look for this problem in journal submission and to ensure constructs are defined and analyzed appropriately.

In terms of antecedents of culture, rhetoric has outpaced rigorous research, although leadership appears to be supported both theoretically and empirically as an antecedent to culture. While recent meta-analytic work (Hartnell et al., 2011) shows relationships between culture and performance, it appears that culture's effects on effectiveness may be more indirect as culture may be both a mediator and moderator of other key relationships.

CLIMATE

This section provides a brief review of the climate construct. We begin by discussing the historical roots and

theoretical underpinnings of the construct, examine the content of climate, and summarize research findings on antecedent and outcome relationships.

Historical Roots and Theoretical Foundations

Climate is widely defined as the perception of formal and informal organizational policies, practices, procedures, and routines (Schneider et al., 2011b). However, the focus of climate research has evolved over the years since Lewin's studies of experimentally created social climates (Lewin, 1951; Lewin et al., 1939). Lewin and his colleagues were interested in examining the climate or atmosphere created by different leadership styles and the consequences these different climates had for the behaviors and attitudes of members in the groups, in this case young boys.

From a theoretical perspective, the relationship between people and their social environment was framed in the formulation: behavior is a function of person and the environment (Lewin, 1951). As such, the environment is created by and/or studied as a construct that is separate from the people who operate within it (Roberts, Hulin & Rousseau, 1978). Climate is an abstraction of the environment that is based on the patterns of experiences and behaviors that people perceive in the situation (Schneider, et al., 2011b). The "agents" (e.g., leaders, management) or factors that create the climate (e.g., structure, strategy, practices) were either assumed or not directly studied (Denison, 1996).

Following the work of Lewin, research in the late 1950s through the early 1970s emphasized the human context of organizations, with particular emphasis on individual-level and organizational outcomes (Schneider et al., 2011b). For example, a number of theorists (e.g., Argyris, 1964; Likert, 1967; McGregor, 1960) suggested that the social context, climate, or atmosphere created in the workplace has important consequences such that the conditions created in the workplace influence the extent to which an employee is satisfied, gives his or her services wholeheartedly to the organization, and performs up to potential in patterns of activity that are directed toward achieving the organization's objectives. Similarly, a number of researchers documented consistency between climates and the needs or personalities of individuals within them (e.g., George & Bishop, 1971; Pervin, 1967) and showed the impact that climates have on the performance and attitudes of individuals that work within them (e.g., Litwin & Stringer, 1968; Schneider & Bartlett, 1968).

Controversies and Resolutions

Despite climate's strong historical foundation, the concept was still somewhat ill-defined and, as work continued throughout the 1970s and 1980s, the construct became plagued by controversies, ambiguities, and methodological difficulties (Kozlowski & Doherty, 1989). These issues centered around the objective versus perceptual nature of climate, and the appropriate level of analysis for addressing climate.

Objective Versus Perceptual Climate and Levels of Analysis

In contrast to the approach based on Litwin's work (that climate was driven largely by leadership and practices), Payne and Pugh (1976) suggested that climate was produced by the objective context and structure of the organization (e.g., size, hierarchy, span of control, resources, and rate of turnover). Controversy continued over whether climate was an objective organizational property or a subjective and perceptual one (Taguiri & Litwin, 1968). A related controversy centered on whether climate was an individual or organizational attribute (e.g., Guion, 1973).

To resolve this issue, a distinction between *psychological climate* when climate is conceptualized and measured at the individual level and *organizational climate* when climate is conceptualized and studied as an organizational variable was proposed (L. R. James & Jones, 1974). In doing so, the original Lewinian basis for climate was extended to include interactionist and cognitive theoretical perspectives. That is, climate was conceptualized as sets of perceptually based descriptions of organizational features, events, and processes. At the individual level, these perceptions represent cognitive interpretations of the context and arise from individuals' interactions with context and with each other (e.g., L. R. James & Jones, 1974; A. P. Jones & James, 1979). Thus, more attention was given to individuals' perceptions than to organizational characteristics, and psychological meaningfulness became an explicit part of the definition (Rentsch, 1990).

A related concern was raised about psychological climate perceptions, questioning whether climate is a measure of affective responses similar to job satisfaction (e.g., Guion, 1973). This issue was resolved through a series of papers showing that climate and satisfaction are conceptually distinct constructs (e.g., LaFollette & Sims, 1975; Payne, Fineman & Wall, 1976; Schneider & Snyder, 1975). To maintain this distinction, given that climate is defined as perceptions of the context, Schneider and his colleagues (Schneider et al., 2011a) propose that climate

items be phrased to be descriptive of the context and not include feelings, affective tone, or internal evaluations of the experience in the environment.

Nevertheless, debate continued into the 1980s over whether *organizational* climate should be measured through objective features of organizations (Glick, 1985, 1988) or through assessments of how individuals perceive the organization (L. R. James, Joyce & Slocum, 1988). James and his colleagues (e.g., L. R. James et al., 1988; L. A. James & James, 1989) argued that since organizational climate arises out of cognitive appraisals and social constructions of individuals, measures of organizational climate should rely on the individual as the basic unit of theory and thus it is appropriate to describe organizations in psychological terms. When consensus among individuals in their perceptions of climate can be demonstrated, the perceptions can be meaningfully aggregated to represent unit or organizational climate (L. R. James, 1982). The distinction between psychological climate as an individual perception and organizational climate as a shared perception is widely accepted today (L. R. James et al., 2008; Schneider et al., 2011a).

Climate Is Not Aggregation Alone

The generally accepted definition of climate is that it is a perception of practices, policies, procedures, and routines in the organization. When these perceptions are shared, climate can be construed as what Ferris, Arthur, and Berkson (1998) refer to as higher-order social structure—a socially interactive context within which individuals operate and that highlights the behaviors and responses that are expected, supported, and rewarded (Schneider et al., 2011b). In our view, simply showing that employees have some degree of consensus around a construct does not necessarily constitute climate. For example, the degree to which team members' share affective responses such as mood, emotion, and affect has been labeled affective climate (e.g., Gamero, González-Romá & Peiró, 2008). As these are not based on perceptions of practices, policies, procedures, and routines, we would conceptualize this as collective affective tone, not as climate.

Similarly, researchers have long recognized the important role of leaders in creating and maintaining climates (e.g., Kozlowski & Doherty, 1989; Lewin et al., 1939; Rentsch, 1990) and have typically viewed leadership as an antecedent of climate. However, some researchers have also viewed leadership as a dimension of climate (Schneider et al., 2011b). Leadership and climate are distinct constructs and blurring of boundaries between the two constructs muddies the construct space and potential

nomological network. For many years, assessments of leaders' style and behaviors have been based on aggregated responses from subordinates or other organizational members. Using a leadership style or behavior measure and terming it climate because it is based on aggregated responses of subordinates (see Chen & Bliese, 2002; Liu & Phillips, 2011; Wallace, Johnson, Mathe, & Paul, in press) is inconsistent with the definitions both of leadership and of climate. While leaders certainly play a role in creating the climate, climate typically entails more than leader behaviors alone. Importantly, in the widely accepted definition of climate as perceptions of practices, policies, and routines (Schneider et al., 2011b), leader behaviors are not included. Our perspective is that the constructs of leadership and climate should be treated separately, and the behaviors and styles of supervisors should be viewed as triggers or antecedents of climate.

The Content and Modes of Conceptualizing Climate

In terms of the content of climate, attempts have been made to determine the dimensions and categories of climate (e.g., Campbell, Dunnette, Lawler, & Weick, 1970; L. A. James & James, 1989; Kuenzi & Schminke, 2009; Ostroff, 1993; Patterson, et al., 2005). Different approaches and terms have proliferated. We provide an overview of the molar, generic, and strategic approaches and attempt to clarify the meaning inherent in these different approaches

Molar Climate and Climate Systems

Early work often focused on global or molar concepts of climate. Based on the Gestalt psychology tradition, Litwin and Stringer (1968) denoted climate as a molar construct that captures the motivational value of the *total* situation and Schneider (1975) provided a general definition of climate perceptions as “psychologically meaningful molar descriptions that people can agree characterize a system's practices and procedures” (p. 474). A similar view was proposed by James and James (1989) in that a higher-order factor underlies measurements of psychological climate, termed PC_g . Because climate perceptions are based on emotionally relevant cognitions, they share a single latent component that reflects the subjective valuations of the environment individuals make in reference to their sense of organizational well-being (L. R. James et al., 2008). Some research has supported the notion that a second-order factor of a molar climate of well-being exists (e.g., Burke, Borucki, Chester, & Hurley 1992; L. A. James & James, 1989). Given its theoretical basis in terms of

well-being, this view of molar climate is likely most relevant for understanding individual-level or collective attitudinal outcomes (Schulte, Ostroff, Shmulyian, & Kinicki, 2009).

The aforementioned view of molar climate is based on an additive, compensatory model. That is, scores on various dimensions of climate (e.g., autonomy, cooperation, leader support, and role stress) are averaged or combined additively. However, as proposed in the first version of this chapter (Ostroff, Kinicki, & Tamkins, 2003) and echoed by Zohar & Hofmann (in press), this view underestimates the complexity of climate in that patterns or configurations based on relative emphasis or priorities likely exist and a patterned approach may more accurately reflect climate. A summed or aggregate score across dimensions also has little practical meaning or utility as it does not allow for isolating the more important dimensions or those that are not in alignment (Schneider et al., 2011a). Thus, a system approach has been proposed to identify the configurations or patterns that exist across multiple dimensions or aspects of climate, that is, the pattern of high and low scores across all climate dimensions (cf. MacCormick & Parker, 2010; Schulte, Ostroff & Kinicki, 2006; Schulte et al., 2009). Each configural system represents the overall pattern of climate across dimensions and can then be related to outcomes of interest. This view of climate is consistent with Tolman (1932), who distinguished between molar and molecular behaviors, with molar being strongly influenced by gestalt psychology and conveying the notion that the whole is more than the sum of the parts in emergent properties.

Generic Climate Dimensions

In addition to molar climate, early attention was devoted to the study of multiple climates within an organization. Research and rhetoric attempted to define a set of broad dimensions thought to best represent the most important aspects of organizational climate that are relevant across organizations. The result has been a proliferation of dimensions, largely without parsimony (Zohar & Hofmann, in press).

Some attempts have been proffered to organize the wide array of dimensions into facets of climate. These approaches attempt to delineate a set of broad-based generalizable facets such as autonomy, structure, reward orientation and consideration (Campbell et al., 1970), leader support, role stress, autonomy and cooperation (L. A. James & James, 1989), or affective, instrumental, and cognitive (Ostroff, 1993) facets with associated dimensions for each facet. As noted by Zohar & Hofmann (in press),

this approach can advance theory by defining the boundaries of climate dimensions. However, additional work is needed to define the boundaries of climate and to compare the utility of these different generic measures of climate.

Strategic Climates

Schneider (1975) concluded the generic approach to climate was too amorphous, inclusive, and multifaceted to be useful. That is, attempting to describe organizational situations simultaneously along 10 or so generic facets has no focus and, thus, relationships to some specific outcome will be modest at best (Schneider et al., 2011b). As an alternative, he offered a strategic approach, proposing that climate be conceptualized and studied as a specific construct that has a particular referent or strategic focus, indicative of the organization's goals (Schneider, 1975). Climate should be conceived of as a "climate for" something (e.g., a climate for service), which can be directly linked to a commensurate specific, strategic criterion or outcome. The underlying premise is similar to that in attitude research (Ajzen & Fishbein, 1975) in that the predictor and criterion variables should not only be conceptually linked, but should also be operationalized at the same level of specificity.

The notion of a strategic "climate for" has gained wide acceptance. For example, researchers have studied climates for safety (e.g., Christian, Bradley, Wallace, & Burke 2009), service (e.g., Liao & Chuang, 2007), sexual harassment (e.g., Offermann & Malamut, 2002), diversity (e.g., McKay, Avery, & Morris, 2009), racial bias (Ziegert & Hanges, 2005), innovation (e.g., Klein & Sorra, 1996), justice (e.g., Mayer, Nishii, Schneider, & Goldstein, 2007), citizenship behavior (e.g., Schneider, Gunnarson, & Niles-Jolly, 1994), ethics (e.g., Victor & Cullen, 1988), empowerment (e.g., Chen, Lam, & Zhong, 2007) voice (Morrison, Kamdar, & Wheeler-Smith, 2011), and excellence (Eisenbeiss, van Knippenberg, & Boerner, 2008).

The advantages of this approach are that it focuses climate around a specific criterion of interest and coupled with the focus on commensurate climates and criteria at the same level of specificity tends to demonstrate stronger validity (Schneider et al., 2011a). That said, the strategic climate approach may be in danger of falling prey to Schneider's (1975) original criticism that the number of dimensions of climate was growing without a uniform approach, as evidenced above in the number of "strategic" climates studied. The impetus behind the strategic climate notion was not to simply study any single aspect of the social context of the organization and label it a "climate

for” but rather that a climate for should be linked to a commensurate and specific strategic outcome reflective of an organizational goal. However, what some researchers label as a strategic “climate for . . .” are often treated in much the same way that generic climate dimensions are treated, linking climate to a broad array of outcomes and mixing levels of specificity (what Zohar and Hofmann, in press, label as domain-specific climate). For example, a climate for justice has been linked to OCB, commitment, job satisfaction, team performance, and team absenteeism (Colquitt, Noe, & Jackson, 2002; Ehrhart, 2004; Liao & Rupp, 2005; Mayer et al., 2007). A climate for empowerment has been linked to feedback-seeking behavior, overall team performance, and individual performance (Chen et al., 2007; Seibert, Silver, & Randolph, 2004; Wallace et al., in press). We urge researchers to carefully consider whether they are capturing a strategic climate or simply adding another single dimension to the large body of climate dimensions.

Integration Among Molar, Generic, and Strategic Climate Approaches

Integrations of molar, generic, and strategic climates are emerging. For example, at the molar level, Burke and his colleagues (e.g., Burke, Borucki, & Hurley, 1992; Burke, Borucki & Kaufman, 2002) propose the existence of multiple higher order climates or multiple PC_gs that combine generic and strategic climates, that is, a higher order climate for well-being and a higher order climate for service. Wallace, Popp, and Mondore (2006) supported the notion that management–employee relations and organizational support climates provide a foundation for safety climate, and Schulte, et al. (2009) combined generic and strategic climate dimensions in climate configurations.

Most recently, Schneider and his colleagues (Schneider et al., 2011a, 2011b) provided a unified framework for integrating generic, molar, and strategic climate. In their conceptualization, generic dimensions (e.g., fairness, participation) represent the latent construct of a molar climate for employee well-being. This molar climate provides the foundation upon which appropriate strategic climates can be built. Another potentially useful framework for integrating climate approaches was developed by Patterson and his colleagues (Patterson et al., 2005) based on Quinn and Rohrbaugh’s (1983) CVF, which was discussed earlier in regard to the content of culture. The climate survey developed based on this framework should allow researchers to simultaneously consider multiple types and approaches to climate as well as to make comparisons between culture and climate.

Antecedents of Climate

More attention has been directed toward studying the outcomes of climate than to understanding the factors that influence climate, although this has been changing in recent years. Based on an extensive review, Payne and Pugh (1976) proposed a model indicating how organizational climate was produced from context (e.g., purpose, size, resources, technology) and structure (hierarchy, authority system, structuring of role activities). While early research only modestly supported this model (e.g., A. P. Jones & James, 1979; Payne & Pugh, 1976), more recent developments, and the conceptualization of climate around a specific strategic focus, have shown stronger results. For example, Lindell and Brandt (2000) revealed that climate mediated the relationship between a number of antecedents such as formalization, leadership and team process, and outcomes such as attitudes and turnover. The context, organizational practices, and leadership are potentially important antecedent variables that can be gleaned from the literature.

Organizational context variables have shown promise for understanding climate. For example, technical, structure, and reward systems have been related to a climate for technical updating (Kozlowski & Hulst, 1987). Organizational-level variation in age has been shown to be important for organizational climate of age discrimination (Kunze, Boehm & Bruch, 2011) and the demographic composition of the organization has been related to women’s psychological climate perceptions of gender inequity across various occupations (King, Hebl, George, & Matusik, 2010). At the team level, team size and team collectivism have been shown to be significant antecedents of team climate of justice (Colquitt et al., 2002). Some work has also explored the impact of the external context on climate, such as the degree of violence in the surrounding community for procedural justice climate (Dietz, Robinson, Folger, Baron, & Schulz, 2003) and the racial composition of the community in which the organization is located for diversity climate (Pugh, Dietz, Brief, & Wiley, 2008).

Human resource management practices have been particularly emphasized as a factor that drives climate (e.g., Kopelman, Brief, & Guzzo, 1990; Klein & Sorra, 1996; Schneider, 1990). Recently, research has supported the relationship between human resource practices and organizational climate (e.g., Collins & Smith, 2006; Ngo et al., 2009).

Finally, top management and leaders have been proposed as important direct or indirect factors believed

to influence organizational climate (e.g., Kozlowski & Doherty, 1989; Zohar & Hofmann, in press) due to the fact that managers and leaders are largely responsible for communicating meaning (Schein, 2010). However, leadership has not been a primary focus in climate research until recently (Schneider et al., 2011b). Leaders' personality has been related to individuals' perceptions of justice climates (Mayer et al., 2007) and to unit service climate (Salvaggio, Schneider, Nishii, Mayer, Ramesh, & Lyon, 2007). In terms of ethical climate, leader's moral development (Schminke, Ambrose, & Neubaum, 2005) and consideration and initiating structure (Mulki, Jaramillo, & Locander, 2009) have been related to perceptions of ethical climate. Leadership style has also been shown to influence climate (e.g., Ehrhart, 2004; Liao & Chuang, 2007). In a theoretical treatment, Dragoni (2005) argued that a leader's goal orientation and related patterns of behaviors provide cues to subordinates to influence the development of goal-oriented climates in groups. Additional issues pertaining to formation and consensus of climate perceptions are addressed later in the climate emergence section.

Outcomes of Climate

A wide variety of climates have been related to various attitudinal and performance-based outcomes. By far, the most studied group of climate outcomes are those experienced by individuals in the workplace, although a growing body of work has examined relationships between group or organizational climate and group or organizational outcomes.

Individual-Level Outcomes

Two types of studies have been conducted to examine the impact of climate on individual outcomes: (a) individual-level studies examining relations between psychological climate perceptions and individual outcomes and (b) cross-level studies whereby aggregated unit or organizational climate scores are related to individual outcomes. Two meta-analyses have demonstrated consistent relationships between psychological climate and individual outcomes. Using Ostroff's (1993) typology, Carr, Schmidt, Ford, and DeShon (2003) demonstrated that three higher order facets of climate (affective, cognitive, and instrumental) were related to job performance, stress, well-being, and withdrawal through their relationship on commitment and satisfaction. Similarly, psychological climate showed significant relationships to motivation and performance, which were fully mediated by attitudes (Parker et al., 2003).

Moreover, individuals' perceptions of strategic climates have also been related to affective and behavioral outcomes. For example, meta-analytic results indicate that perceptions of climate for safety are related to commitment, satisfaction, safety behaviors, and accidents (Beus, Payne, Bergman, & Arthur, 2010; Christian et al., 2009; Clarke, 2010). Perceptions of climate for service friendliness have been shown to be an indicator of displayed emotions of employees (Tsai, 2001), while climate for tolerance of sexual harassment has been related to attitudes and reports of harassment incidents (e.g., Offermann & Malamut, 2002).

Subunit and Organizational-Level Outcomes

Climate for service and climate for safety have been the most consistently examined climates "for" at unit and organizational levels. Studies examining climate for service have shown relationships to customer satisfaction (e.g., Mayer Ehrhart, & Schneider, 2009; Schneider, Salvaggio, & Subirats, 2002), customer perceptions of service quality (e.g., Schneider, White, & Paul, 1998), and unit performance (e.g., Jong, Ruyter, & Lemmink, 2004). In terms of climate for safety, group and organizational climate for safety have been related to a variety of indices of safety behaviors and accidents (Beus et al., 2010; Christian et al., 2009). Additional climate dimensions have also been examined. For example, team climate of procedural justice has shown significant relationships to team performance and absenteeism (Colquitt et al., 2002). Climate for innovation has been found to relate to team creativity (Pirola-Merlo & Mann, 2004) and organizational product innovation (Patterson et al., 2005). Generic climate dimensions have also been related to organizational effectiveness (e.g., Lindell & Brandt, 2000; Ostroff & Schmitt, 1993). Finally, climate systems, operationalized as configural patterns of climate, have been linked to customer satisfaction and financial performance, whereas overall climate was related to employee attitudes (Schulte et al., 2009).

Mediators, Moderators, and Boundary Conditions

In Figure 24.1, climate is positioned as a mediator between practices and employee responses and performance outcomes. In recent years, this linkage has been tested and supported at the organizational (e.g., Collins & Smith, 2006; Rogg et al., 2001; Takeuchi, Chen, & Lepak, 2009) and unit level (e.g., Chuang & Liao, 2010). In addition, at the unit level of analysis, climate has also been shown to mediate the relationship between leadership style and

citizenship behaviors at the group level (Ehrhart, 2004) and individuals' commitment (Walumbwa, Hartnell, & Oke, 2010).

Importantly, in recent years, research has moved from demonstrating a relationship between climate and outcomes toward examining the process through which climate has its effect on outcomes (Schneider et al., 2011b). In support of the linkages in Figure 24.1, collective attitudes, motivation, and behaviors have been shown to be mediators between climate and performance outcomes at the organizational level (e.g., Patterson, Warr, & West, 2004), group level (e.g., Neal & Griffin, 2006; Schneider, Ehrhart, Mayer, Saltz, & Niles-Jolly, 2005), and individual level (e.g., Carr et al., 2003; Parker et al., 2003). Also consistent with Figure 24.1, psychological climate has been shown to be a mediator between unit-level climate and individual outcomes (e.g., Seibert et al., 2004).

Climate has also been examined as a moderator that can compensate for lower levels of some organizational attributes or that can enhance the effectiveness of organizational attributes. For example, climate was shown to compensate for low level of leader attributes in terms of providing service to internal customers (Hui, Chiu, Yu, Chen, & Tse, 2007), unit performance (Fay, Lührmann, & Kohl, 2004), and team innovation (Eisenbeiss et al., 2008). In contrast, other studies have shown that climate facilitates or enhances organizational attributes (e.g., Grizzle, Zablah, Brown, Mowen, & Lee, 2009; Hofmann, Morgeson, & Gerras, 2003; Walumbwa, Peterson, Avolio, & Hartnell, 2010).

Finally, some research has begun to explore boundary conditions under which climate operates (e.g., Van der Vegt, Van de Vliert, & Xu, 2005; Yang, Mossholder, & Peng, 2007). As an illustration, the positive effect of a unit-level climate for service on customer outcomes depended on service-related variables such as frequency of customer contact and service intangibility (Dietz, Pugh, & Wiley, 2004; Mayer et al., 2009a). We encourage more research along these lines to help develop a deeper understanding of the relationship between climate and outcomes as well as theoretical treatments to develop a more parsimonious framework for understanding mediators and moderators of climate.

Conclusion

Despite the now widely accepted definition of climate as a summary perception or summated meaning that people attach to particular features of the work setting, and the growing body of work elucidating the important

role that climate plays in understanding organizational functioning, work is still needed in this area. It is generally acknowledged that multiple types of climate exist within an organization (e.g., Schneider et al., 2011b) and that organizations operate in multiple performance domains (e.g., Cameron, 1978). Yet, the work on climate “fors” has tended to examine one climate “for” at a time. The recent theoretical and empirical work that combines generic or foundational climates with strategic climates (e.g., Clarke, 2010; Patterson et al., 2005; Schneider et al., 2011a, 2011b) provides a fruitful avenue for future research. Further, the climate system approach has the potential to better capture the totality of climate while at the same time retaining the relative importance of various facets of climate. Different configurations of climates are likely to be related to effectiveness outcomes in different performance domains (Schulte et al., 2009), but more work is needed in this area.

Important research is also being conducted to elucidate the antecedents of climate; however, this work has not been conducted systematically. We identified three areas of potential antecedents—context, practices, and leadership. The relative importance of these factors in determining climate is largely unknown. Further, understanding the intersection of practices and leadership in creating climates is needed. Finally, interesting research has begun to examine climate as a mediator and moderator. There is additional research on how and why climate relates to outcomes as well as on the boundary conditions under which climate has its effects.

RELATIONSHIP BETWEEN CULTURE AND CLIMATE

There are several key issues to consider when discussing the relationship between culture and climate. We begin with the theoretical and empirical overlap between the constructs and propose that organizational practices are the linking mechanism that mediates the relationship between culture and climate. We then explore levels of analysis issues and data aggregation.

Overlap and Confusion Between Culture and Climate

Although researchers traditionally made theoretical distinctions between culture and climate, a number of articles have explored what differentiates these concepts (cf. Denison, 1996; Payne, 2000; Schein, 2000; Schneider et al., 2011b; Zohar & Hofmann, in press). Traditionally, culture

was studied with qualitative methodologies using case studies while climate research has been largely quantitative and survey-based, asking employees about their perceptions of the organizational context. However, in more recent years, many empirical culture studies have become virtually indistinguishable from traditional climate research (Boggs & Fields, 2010). We believe the root cause for the blurring of culture and climate stems, not so much from theoretical treatments, but from empirical attempts to assess the constructs.

Two types of studies have contributed to the overlap between climate and culture. First, during the 1990s, a number of quantitative “culture” studies began appearing, using a survey-based methodology much like that of climate (e.g., Chatman, 1991; Cooke & Szumal, 1993), often focusing on the same dimensions originally investigated in climate research (e.g., support, achievement, innovation). In the culture literature, these dimensions (e.g., support, innovation, achievement) are often referred to as “values,” while in the climate literature they are often referred to as climate dimensions or the organizational context. We argue that, in these studies, the “why” of culture and “what” of climate are not clearly distinguished. The second research stream that has contributed to the blurring of these constructs is culture studies that focus on quantitative assessments of perceptions of organizational practices (e.g., Hofstede, 1998; Hofstede et al., 1990; van Dyck, Frese, Baer, & Sonnentag, 2005). The items and dimensions assessed in these studies are often very similar to traditional climate research and more closely resemble climate as the perceptions of practices, policies, and procedures.

These types of studies tend to focus on what Schein (2010) terms *artifacts* and represent an overlap between research in climate and culture. We argue, similar to others, that artifacts are the overlapping area between climate as perceptions of practices and culture as deep-rooted assumptions and values. Climate can be viewed as a representation of enacted values, and a comparison between espoused and enacted values helps inform employees about the basic assumptions and core values (Zohar & Hofmann, in press).

Organizational Practices: The Linking Mechanism Between Culture and Climate

Practices, policies, procedures, and routines play a role in both culture and climate. They are viewed as artifacts in culture (Schein, 2010) while in the climate literature (e.g., L. R. James, 1982; Schneider & Reichers, 1983)

they are viewed as the basis for the formation of climate perceptions. We propose that the set of actual practices, policies, and procedures is the linking mechanism between culture and climate (see Figure 24.1), *not* a measure of either culture or climate.

Several researchers and theorists (e.g., Carroll et al., 2011; Kopelman, Brief, & Guzzo, 1990) assert that the organizational practices, management practices, policies, and procedures (hereafter referred to generically as “practices”) adopted in an organization reflect cultural influences. Similarly, other work has examined the degree of (in)congruence between culture and actual organizational practices and has taken this to be a measure of culture “consistency” or “alignment” (e.g., Denison, 1990; Zohar & Hofmann, in press). That is, alignment between culture and practices is a separate variable or construct. This implies that (a) culture is not practices and (b) culture should lead to a set of practices, policies, procedures, and routines that are consistent with the underlying cultural values (e.g., Kopelman et al., 1990). To the degree alignment is achieved, organizational functioning and effectiveness should be enhanced (Chow & Lin, 2009; Schein, 2010).

However, alignment between culture and practices is not sufficient for organizational effectiveness. Organizational members must perceive the practices in a manner consistent with the underlying values and intended strategic goals (Chow & Liu, 2009; Ostroff & Bowen, 2000). Therefore, culture can lead to a set of relevant practices that are then perceived by organizational members as climate. For example, a set of reward practices about how to treat customers, selection standards, and so forth may be adopted to be consistent with a culture that values the customer. To the extent that organizational members perceive these practices to be consistent with a service focus and agree among themselves on their perceptions, a service-based organizational climate is said to exist in the firm (Schneider, 1990). This suggests the importance of “practices” as a mediating mechanism for linking culture and climate (Kopelman et al., 1990). Further, it suggests that inconsistencies between culture and climate are likely to have occurred through some misalignment or poor implementation of the set of practices. If the adopted practices do not reflect the culture, or if practices are poorly implemented, climate perceptions may develop that are counter to the underlying cultural values and assumptions (Bowen & Ostroff, 2004). In addition, these climate perceptions provide employees with direction and orientation about where they should focus their skills, attitudes, and behaviors in pursuit of

organizational goals (Schneider et al., 1994). As implied in Figure 24.1, alignment between culture, practices, and climate is necessary for employees to respond and behave in ways that will lead to organizational effectiveness (e.g., Ostroff & Bowen, 2000).

MOVING ACROSS LEVELS OF ANALYSIS

In the culture literature, the term *levels* has been used frequently to discuss the different layers of culture (artifacts, values, assumptions/ideologies) identified by Schein (1990). In the climate literature, the term *levels* has been used in a manner consistent with the levels of analysis literature, that is, distinguishing between hierarchical levels in the organization (e.g., Klein, Dansereau, & Hall, 1994). Here, we use the term *levels* to refer to the organizational levels of analysis literature, and we distinguish between the individual, subunit (e.g., group, division, plant, function), and organizational level. We use the terms *organizational* or *unit level* generically to refer to higher level constructs.

More attention needs to be placed on levels of analysis issues in the culture literature. Culture is a unit-level construct and it has been studied at various hierarchical unit levels (e.g., societies, organizations, departments, stores). Although all of these units are legitimate levels from which to study organizational culture, limited research has been devoted to elucidating how culture comes to be understood across an entire organization or within different categorical units or subcultures (e.g., Hatch, 2011). This is unfortunate because a multilevel process takes place in culture emergence and change but the multilevel nature is underexplored. It also is important to reinforce the previously noted problem of studying this unit-level construct at the individual level of analysis, thereby creating a levels-of-analysis problem.

In the climate area, levels issues have been made explicit. A levels-based distinction has been made between psychological climate and organizational climate (L. R. James & Jones, 1974) with the relationship between them viewed as compositional. That is, there is isomorphism in the manifestations of the construct at different levels of analysis whereby the constructs share the same content, meaning, and construct validity across levels of analysis (Chan, 1998; L. R. James et al., 2008; Kozlowski & Klein, 2000). Because researchers have acknowledged that climate is based on the psychological meaning of the situation to individuals, the unit of measurement begins with the individual. Only when these

perceptions are shared across people does organizational climate become a meaningful construct (e.g., L. R. James et al., 2008).

Further, there is the assumption that different cultures and climates can exist at different organizational levels of analysis in the form of subcultures (e.g., Hofstede, 1998; Martin & Siehl, 1983) and subclimates (e.g., Schulte, 2007). We acknowledge that the specific content of culture and climate can vary across groups within an organization and return to the implications of this after exploring the notion that climate and culture are emergent properties of organizations.

Shared Meaning and Perceptions

Shared meanings and perceptions are the foundation of organizational level or unit-level culture and climate. We discuss a variety of issues associated with the methods used to establish the extent of shared meaning or convergence of perceptions.

Demonstrating Agreement

Both qualitative and quantitative approaches have been used to demonstrate agreement in the culture literature. Some culture researchers elicit interpretations of what the organizational context means to employees (e.g., Langan-Fox & Tan, 1997) and, from these assessments, summarize meaning into some aggregated qualitative description of the culture. The qualitative method does not well allow for objective comparisons across units or for direct assessment of the extent of agreement. For those who examine organizational culture with surveys, many researchers assess culture via single respondents from the participating organizations, generally the CEO (e.g., Kinicki et al., 2011). A few researchers have relied on methods that assess culture with multiple respondents from a single unit and have adhered to procedures established in the levels-of-analysis literature to support the aggregation of unit-level culture scores (Hartnell et al., 2011). Two criteria should be evaluated. The first rests on demonstrating between-group differences between units on their mean scores. The second pertains to establishing within-unit agreement as a means that culture exists because individuals interpret and make sense of the environment similarly (Yammarino & Dansereau, 2011).

In contrast to the culture literature, climate researchers have devoted considerable attention to documenting the degree to which organizational members share perceptions of the organizational climate, and fundamental controversies over the “aggregation problem” have largely been

resolved (cf. Bliese, 2000; Chan, 1998; Klein et al., 2000). The most common procedure is to use a mean or aggregated score across individuals within the same unit to represent a higher-level climate. Researchers have long applied the same two criteria mentioned above (between-group differences and within-unit agreement) to show that psychological climate, operationalized at the individual level, is functionally isomorphic to another form of the construct (e.g., organizational climate) at the higher level. Recently, there has been some question regarding which particular statistic to use to demonstrate sufficient consensus among perceptions in order to justify aggregation (cf. Burke, Finkelstein, & Dusig, 1999; L. R. James, Demaree, & Wolf, 1984; LeBreton, James, & Lindell, 2005; LeBreton & Senter, 2008).

A related issue pertains to the referent or focal point for assessing climate. Traditional assessments of climate (e.g., L. R. James & Jones, 1974) tended to have the focal point of measurement as the individual (e.g., I perceive...) using a direct consensus model (Chan, 1998). James and his colleagues (e.g., L. R. James, 1982; L. R. James et al., 2008) purport that the individual, not the group or organization referent, is the most appropriate frame for assessing climate because climate is based on an individual's own perception of the context; when perceptions across individuals are shared, the construct of climate has meaning at a higher level of analysis. In recent years, however, many researchers have argued for a referent-shift model (Chan, 1998). Rather than measure an individual's own climate perceptions, the item referent is the unit or group as a whole or how an individual believes most people in the organization perceive the climate (e.g., Klein, Cohn, Smith, & Sorra, 2001; Kunze et al., 2011; Mayer et al., 2007; Morrison et al., 2011). That is, the conceptualization of the climate construct is still at the level of individual perception, but the referent of the content is changed to the unit level (from self to others), with the rationale being that the unit of analysis is the higher level, hence a group or organizational referent is more appropriate. The distinction between direct consensus and referent shift models is more than semantics. Asking individuals to focus on the unit as whole, and take themselves out of the equation, removes the individual and may mask one source of individual variation from the unit-level assessment, whereas asking individuals their own idiosyncratic perceptions and then demonstrating shared agreement to give rise to unit climate situates climate as shared idiosyncratic climate perceptions. Clearly, more theory and research is needed to determine the implications of this shift in focal

point and the use of group-based agreement techniques for the construct meaning of climate across levels of analysis.

(Dis)agreement

The absence of shared perceptions has been addressed in both the culture and climate literatures. For example, the deviance model (Martin, 1992) or the dissensus model (Trice & Beyer, 1993) of culture highlights disagreement or lack of consensus. However, there is debate as to whether deviance or dissensus in an organization indicates whether a culture exists, a fragmented culture exists, or no culture exists.

In the climate literature, to the extent homogeneity in perceptions of climate is present, collective perceptions and responses should be more uniform and organizational-level relationships can emerge and be meaningfully examined (Ostroff & Bowen, 2000). Large variability in perceptions among members indicates that aggregated perceptions do not adequately represent a construct of climate at the higher level (e.g., L. R. James et al., 2008; Klein et al., 2000), hence only individual-level relationships are meaningful.

Empirical studies of climate have often found that while agreement on climate may be adequate from a methodological standpoint to justify aggregation, there is a still considerable variability in perceptions, and some groups or organizations in the sample have less than adequate agreement on climate perceptions (cf. Colquitt et al., 2002; González-Romá, Peiró, & Tordera, 2002; Zohar & Tenne-Gazit, 2008). Thus, dispersion models (e.g., Chan, 1998; Kozlowski & Klein, 2000) have been proposed whereby the degree of variability in responses represents an important variable in its own right (not only justification for an aggregate score), independent of the "level" of the content of climate (e.g., mean climate on some climate dimension). Issues pertaining to variability and homogeneity are discussed in the following section as they pertain to the emergence of culture and climate.

EMERGENCE OF SHARED MEANING AND PERCEPTIONS

Culture and climate are viewed, at least partly, as emergent properties of organizations. As defined by Kozlowski and Klein (2000, p. 55), "A phenomenon is emergent when it originates in the cognition, affect, behaviors or other characteristics of individuals, is

amplified by their interaction, and manifests as a higher level, collective phenomenon. . . .” Two distinct dimensions of emergent processes are delineated: elemental content and interaction. Elemental content is the raw material of emergence and refers to the cognitions, affect, perceptions, or mental representations. Interaction denotes the process of emergence (e.g., how elemental content becomes shared) through communication and information exchange, sharing of ideas, exchanging work products, and other forms of interactions among employees. In combination, the elemental content and form of the interaction process comprises the emergent phenomenon. When group members share the same schema for important work-related events, it enables them to act more effectively and efficiently with one another and within the context of the situation (Schneider, 1975). Thus, it is important to understand *how* similar “cognitive maps” (Weick, 1995) can be created across people, thereby allowing an analysis of the situation as a whole as opposed to individual differences in the perception of situations (Magnusson & Endler, 1977).

Emergence of Organizational Culture

Hatch (1993, 2011) proposed a systems model to explain how Schein’s (2010) organizational layers—artifacts, espoused values, and assumptions—dynamically interact to influence organizational sense making. Trice and Beyer (1993) also argued that individuals use sense making processes to interpret a unit’s values, beliefs, and assumptions. Although this work enhances our knowledge about the elemental component of culture by describing how unit members derive meaning from their work environments, it does not well explain how a shared view of an organization’s culture emerges or comes to exist. Schneider and Reichers (1983) focus on emergence as a process of attraction, selection, and attrition whereby new members are initially drawn to the organization based on the founder’s values and goals, are selected by the initial group of management based on having values consistent with those of the founder, and leave if they do not fit in the organization, a process that creates homogeneity and allows for emergence of a shared sense of culture. However, emergence of a shared view of culture also requires the modeling of interactions into the sense-making process.

Hartnell and Kinicki (2011) pursued this recommendation by developing a model that attempts to explain how the pattern of interactions between leaders and their unit members leads to culture emergence in nascent work units.

The focus on nascent units, as opposed to existing ones, is important because culture first emerges during the founding stages of an organization and thereafter becomes a unit-level property that might be further shaped. Hartnell and Kinicki integrated self-regulation theory (Carver & Scheier, 1998) and event-structure theory (Allport, 1954) to explain how leader–unit member interactions create consensus about values, beliefs, and assumptions in nascent work units over time. Their fundamental proposition is that culture emergence is a learning process based on the by-products of unit members’ vicarious and experiential learning. Bass and Avolio (1994), Keith and Frese (2011), and Schein (2010) similarly concluded that unit-level learning is fundamental to culture emergence.

Culture emergence ultimately results from a sense making process of leaders’ regulatory behaviors, members’ regulatory behaviors, and leader–member interactions. Similar to Schein (2010), leader regulatory behaviors include planning, organizing, monitoring, evaluating, and correcting unit behavior in the pursuit of unit-level goals, and vicarious norms refer to learned behavioral expectations derived from listening to leaders and observing their regulatory behavior. This perspective clearly frames culture emergence around a vision or purpose, specifically unit goals. Unit regulatory processes are predicted to lead to experiential learning (i.e., learning based on experience or the consequences of a unit’s goal-directed behavior) and shared mental models of effective behavior. Shared mental models represent a shared understanding and mental representation about the important contextual elements (Mohammed, Ferzandi, & Hamilton, 2010). Shared mental models are expected to foster experiential norms because they create consensus regarding normative expectations about future behavior (Bettenhausen & Murnighan, 1985).

Leader–member interactions are the critical linchpin within Hartnell and Kinicki’s (2011) model because they drive consensus about the values, beliefs, and assumptions. Maitlis and Lawrence (2007) refer to leader–member interactions as *sense giving*. They define sense giving as an interpretative process “in which actors influence each other through persuasion or evocative language” (p. 57). Hartnell and Kinicki (2011) view leader–unit member interactions more broadly in scope than Maitlis and Lawrence in that they are directly tied to reconciling performance discrepancies (i.e., gaps between goals and actual performance) that occur over time. Leader–member interactions involve bidirectional discourse through which leaders and members affirm appropriate behavior or identify and clarify informational

discrepancies. Leaders promote two-way communication through coaching and delivering performance feedback. Members similarly propagate bilateral communication through sharing operational feedback with their leaders. These leader–member interactions identify gaps between vicarious and experiential norms, clarify behavioral expectations, and create consistent signals about appropriate and effective behavior.

The system of interactions between leaders and members is consistent with event structure theory (Allport, 1954). Event cycles represent a continual cyclical relationship between *ongoings* (everyday activities for leaders and members), and *events* (discrete interactions or circumstances that cause a significant disturbance to members' routines or pursuits toward goal accomplishment). Hartnell and Kinicki (2011) use event structure theory to describe how event cycles and their underlying repeated interactions between leaders and members create consensus about values, beliefs, and assumptions. They propose that leaders and members spend more time in *ongoings* than *events* over time, which serves to build consensus. Further, through the event cycles vicarious learning and experiential norms develop, producing consistent information about desired behavior, allowing for a shared culture to emerge.

There is one last issue to consider regarding culture emergence. Specifically, once culture has emerged, culture no longer originates in the cognitions, affect, or behaviors of individuals. Rather, “postemergent” culture stems from collective, mental models, affective states, and behaviors. This implies that events triggering culture-related event cycles after a state of emergence represent issues, information, or performance discrepancies that may modify or reshape the culture.

Very little is known about the process of culture emergence beyond theory on sense making (e.g., Hatch, 1999; 2011; Trice & Beyer, 1993; Weick, 1995). Future research is needed to test the propositions underlying Hartnell and Kinicki's model and to consider alternative theoretical explanations of culture emergence.

Emergence of Organizational Climate

The formation of climate has been regarded primarily as an individual-level process based on sense making and cognitive representations of meaning inherent in organizational features and processes (Schneider, 1983). This process, however, has also been viewed as interactive and reciprocal (Ashforth, 1985; Kozlowski & Doherty, 1989; Schneider, 1983).

Unit and organizational climate are viewed as emergent properties and as such may capture more than the sum of the individual parts (Kozlowski & Klein, 2000). In sociology, there is long tradition of studying emergence as a group effect whereby the group attribute has effects beyond a commensurate individual attribute (Blau, 1960). Some demonstration that higher-level climate is an emergent property that demonstrates group effects comes from studies showing that the aggregate higher level climate has effects on individuals beyond their own psychological perceptions of climate (e.g., Schulte et al., 2006; Spell & Arnold, 2007).

It is important to note that emergence is related to what has been referred to as agreement-based strength (Ostroff et al., 2003), which refers to the agreement on climate (Lindell & Brandt, 2000; Schneider et al., 2002). For a climate to have emerged, a reasonable degree of consensus in perceptions is needed (L. R. James et al., 2008) and, from there, the amount of variance in those perceptions can be taken to indicate how strong the emergent climate is. Below we address structure and practices, homogeneity, interaction processes, leadership, and work-group influences as factors that influence emergence of climate.

Structure and Practices

In the structuralist perspective, climate arises out of structural characteristics of an organization. With its roots in Lewin's (1951) field theory, this approach assumes that organizational characteristics such as size and structure establish a common reality that provides the basis for shared perception. Little work has specifically addressed how structural components facilitate emergence, although team size has been shown to be related to the extent of agreement in justice climate (Colquitt et al., 2002) and the degree of formalization important for safety climate (Zohar & Luria, 2005).

More consistent with current definitions of climate, the set of policies, practices, and procedures of the organization are the features that provide the basis for shared perceptions to emerge. However, merely introducing and implementing a set of practices around some strategic focus is not sufficient. Unless the practices are designed and implemented in such a way as to create a strong situation (Mischel, 1973), idiosyncratic psychological climate perceptions are likely to emerge (Ostroff & Bowen, 2000). To the extent that the situational stimulus is ambiguous or unclear, multiple categorization is likely (Feldman, 1981) and different people are likely to use different cognitive categories to attend to different aspects of the situation, making subsequent attributions and responses different.

On the other hand, collective sense making can occur when practices are designed to induce a strong situation, regardless of the type of practice implemented. Bowen and Ostroff (2004) proposed a set of meta-characteristics of HRM systems around three foci: consistency, whereby practices represent a coherent and internally consistent whole; visibility, such that practices are made very visible and salient; and consensus, with practices communicated widely and clearly and administered consistently throughout the organization. These meta-characteristics of the practices purportedly help reduce ambiguity and enhance clarity of interpretation in the setting, thereby allowing for similar “cognitive maps” to develop across people so that the context and appropriate ways of behaving are understood. A strong process of delivering practices creates the elemental content and this content is shared because interpretations are consistent across people. While the particular set of human resource management (HRM) practices should have a strong influence on the content of climate perceptions, the manner in which the practices are delivered should influence the degree of strength or consensus about these perceptions. Some research has begun to develop measures of these constructs and demonstrate the importance of HRM system strength in understanding perceptions and responses (e.g., Bartram, Stanton, Leggat, Casimir, & Fraser, 2006; De Winne, Delmotte, & Sels, 2012).

Homogeneity

This factor of emergence is based on the ASA process (Schneider & Reichers, 1983) in which individuals are attracted to and want to join organizations that have similar attributes to their own views and attributes. Selection procedures attempt to ensure that the applicants hired fit the organizational context, and people tend to leave organizations when the work context does not fit their personal characteristics. As a result, an organization is likely to be comprised of very similar people (Schneider, 1987). These effects may be furthered by the socialization processes that can change new organizational members' personal attributes, goals, and values in the direction of those of the organization (Ostroff & Rothausen, 1997). Due to this homogeneity process, individuals may communicate more frequently, develop stronger ties, and should perceive the organization similarly (Roberson & Colquitt, 2005). Some work has begun to examine relationships between demographic similarity and the degree of consensus or strength of justice climate perceptions, but results have been mixed (cf., Naumann & Bennett, 2000; Roberson & Colquitt, 2005).

Social Interaction and Communication

The third factor that can foster emergence of organizational climate is based on social interaction, with roots in social behaviorism, such that individuals adopt the views of others to enhance their identity (Schneider & Reichers, 1983). Shared perception and meaning evolves from communications and interaction patterns among members of the same group. Overlapping schemas or cause maps across people can be facilitated through social exchange and transactions among employees. As such, they can agree on the appropriate aspects of the environment to attend to, and how to interpret these aspects and respond to them appropriately (Weick, 1995). Through a series of event cycles of interaction and interpretation (Morgeson & Hofmann, 1999), group members construct the meaning of organizational events from repeated social interactions and it is these interactions that are likely to result in conformity (Ashforth, 1985; Luria, 2008).

Social psychologists introduced the notion of social tuning to explain the process through which interactions with others lead to similar attitudes. Achieving a shared reality or a sense that beliefs are shared is thought to establish and maintain social bonds with others (Hardin & Higgins, 1996). Adjusting attitudes and beliefs toward those of others is one manner in which individuals achieve a heightening of shared reality. When individuals desire to get along with others (Sinclair, Lowery, Hardin, & Colangelo, 2005) or desire to acquire knowledge (Lun, Sinclair, Whitchurch, & Glenn, 2007), they are more likely to tune their beliefs to be consistent with those of others (Hardin & Higgins, 1996). Similarly, Venkataramani and Schleicher (2011) show the importance of negative affective ties whereby people distance themselves from individuals they dislike in their social network, thus disrupting the spread of common perceptions.

In support of the social-interaction perspective, the extent of social interactions (González-Romá et al., 2002; Schneider et al., 2002), the density of communication networks (Zohar & Tenne-Gazit, 2008), and the strength of affective ties (Venkataramani & Schleicher, 2011) have been related to the degree of consensus or strength of the climate.

Work Group Processes

As noted earlier, the aggregate level of analysis refers to any higher level (e.g., division, unit). The most immediate and proximal level is likely to have the greatest influence (Rousseau, 1985). For example, a climate of communication at the group level was found to have a stronger relationship to organizational identification

than the department-level communication climate (Bartels, Pruyn, De Jong, & Joustra, 2007). Thus, processes within an individual's immediate work group or team should be of particular importance in the formation of shared perceptions. For example, group processes, such as sharing information, coordinating efforts, interdependence, group identification, and cohesion, have been shown to be important for developing shared perceptions of climate (e.g., Luria, 2008; Naumann & Bennett, 2000; Roberson, 2006).

Leadership

Leaders are likely to play a particularly important role in the emergence of and consensus of climate perceptions. Leaders or supervisors serve as interpretative filters of relevant organizational processes, practices, and features for all group members, contributing to the development of common climate perceptions (Kozlowski & Doherty, 1989). By exposing employees to the same policies, practices, and procedures, they act as "climate engineers" (Naumann & Bennett, 2000) or "climate embedders" (Schein, 2010).

The specific mechanisms through which leaders enhance consensus in perceptions are not well understood. The patterns of leader behaviors can be interpreted by members to elucidate the leader's priorities and shape the climate (Dragoni, 2005). Further, communication from leaders is likely to be one key means for developing convergence in climate perceptions (González-Romá et al., 2002). Leaders explicitly and directly communicate their own interpretations and, in conjunction with interacting with most members, will be able to introduce a common interpretation among unit members (Rentsch, 1990). Using a technique called concept mapping, Marks, Zaccaro, and Mathieu (2000) showed that leader communication in the form of transmitting, exchanging, reporting, and/or passing on information about the task and work environment, as well as training focused on team interaction, were related to the development of shared mental models about how the work system and environment operates. Similarly, the rationale behind the finding that transformational leaders create greater climate consensus is that transformational leadership is characterized by fostering closer relationships with subordinates, creating opportunities to share and clarify perceptions (Zohar & Luria, 2004; Zohar & Tenne-Gazit, 2008). In addition to communication, the visibility of the leader (Naumann & Bennett, 2000), simpler behavioral patterns, and consistency in behavior (Zohar & Luria, 2004) have also been shown to develop greater consensus in climate perceptions (Naumann & Bennett, 2000).

Finally, according to leader-member exchange (LMX) theory, the quality and type of relationship the leader develops with his or her subordinates may be unique across group members (Graen & Scandura, 1987), resulting in LMX differentiation at the group level, that is, variance in the dyadic exchange relationships across group members (Liden, Erdogan, Wayne, & Sparrowe, 2006). Greater LMX differentiation will likely hinder the development of consensus in climate perceptions. Higher quality LMX relationships tend to be characterized by greater information exchange and more attention from the leader (Graen & Uhl-Bien, 1995). Further, leaders have been shown to be a potent source of information for newcomers' learning about the appropriate role behaviors and about the processes, routines, and value system of the organization (Ostroff & Kozlowski, 1992). Likewise, some evidence indicates greater consensus in climate perceptions among those with higher quality LMX relationships in the group compared to those with low-quality LMX relationships (Kozlowski & Doherty, 1989). Thus, to the extent that there is differentiation in the quality of LMX relationships in the group, interactions may be concentrated around select members who have higher quality LMX relationships, producing uneven relational exchanges with the leader and among coworkers (Henderson, Liden, Glibowski, & Chaudhry, 2009; Sherony & Green, 2002) and ultimately leading to dissimilarity in members' climate perceptions (Roberson & Colquitt, 2005). The role of the leader in the emergence of climate perceptions continues to be an area ripe for research.

Implications and Research Directions

Elemental content differs between culture and climate. For example, the cognitions, interpretations, and schema are based around the policies, practices, procedures, and routines in climate (Schneider & Reichers, 1983), whereas, in culture, they are based on artifacts, values, beliefs, and assumptions (Schein, 2010; Trice & Beyer, 1993). Further, culture and climate are said to have emerged when perceptions come to be shared. However, the notion of compilation for climate (Kozlowski & Klein, 2000) is based on the assumption that organizational practices, policies, procedures, the socialization process, ASA process, and related processes are not so strong as to eliminate all meaningful differences in individual members' elemental characteristics, such as their cognitions, perceptions, and behaviors. For example, some organizations may purposefully desire to build an organization that has some heterogeneity of employees in order to create flexibility or promote change (Schneider & Reichers, 1983), or may purposefully select

individuals for their varying idiosyncratic strengths that blend with others (Ostroff & Schulte, 2007). While too much variability in fundamental elements would indicate either no climate or culture, or a fragmented climate or culture, some heterogeneity in individual elements does not preclude the emergence of a collective property (Kozlowski & Klein, 2000). Once sufficient agreement or consensus has been demonstrated and climate has emerged, the degree of strength can be examined.

The emergent property of organizational culture or climate can be strong or weak. The general notion of strong-versus-weak situations is largely derived from Mischel (1973) such that situations are strong to the degree that “they lead all persons to construe the particular events the same way, induce uniform expectancies regarding the most appropriate response pattern, provide adequate incentives for the performance of that response pattern, and instill the skills necessary for its satisfactory construction and execution” (p. 276). Weak situations are ambiguously coded or not uniformly interpreted across individuals, do not generate uniform expectancies concerning the desired behavior, do not offer sufficient incentives for performance, and/or fail to provide the learning needed for behaving appropriately.

The terms *strong culture* and *strong climate* have emerged in the literature, but with the exception of climate strength, have not been defined in consistent ways. We delineate three aspects of strength that encompass strong situations:

1. Agreement-based strength, dealing, with the extent to which employees interpret and encode the organizational situation in the same way, that is, the extent of agreement on culture or climate (e.g., Lindell & Brandt, 2000).
2. System-based strength pertaining to the notion that culture or climate is pervasive and all-encompassing throughout the entire domain of organizational life, imposes strong expectations on employees, and attempts to induce uniform behaviors through strong socialization and sanctions for behaving outside norms (e.g., Payne, 2000).
3. Alignment-based strength, referring to the alignment between culture and actual organizational practices (e.g., Zohar & Hofmann, in press) and between organizational practices and climate (e.g., Rogg et al., 2001).

Agreement-Based Strength

In culture, agreement-based strength is facilitated through the learning and sense making process (e.g., Hartnell and

Kinicki, 2011), but little research has empirically examined this process. In contrast, in recent years, there has been a burgeoning interest in understanding agreement-based strength in climate. The perspectives delineated above for emergence (structural, homogeneity, social interaction, work group, and leadership) also influence the strength of the climate. Agreement-based strength is fostered when (a) practices are administered in a way that allows individuals to interpret them similarly (e.g., Bowen & Ostroff, 2004), (b) members are homogeneous and thus predisposed to view the organization similarly (e.g., Colquitt et al., 2002), (c) shared interpretations are developed through social interactions (e.g., Roberson & Colquitt, 2005), and/or (d) leaders serve as a filter and communicator of practices, policies, and procedures to influence members to interpret the situation the same way (e.g., Zohar & Luria, 2004).

In addition to studies that have begun to facilitate our understanding of the factors that influence climate strength, research has begun to address linkages between agreement-based climate strength and outcomes. Lindell and Brandt (2000) proposed that climate strength (i.e., variance in perceptions) will have direct effects because the similarity in perceptions will lead to more positive typical behaviors across group members. Some research has supported direct effects of climate strength on unit-level outcomes (e.g., González-Romá et al., 2002; Sowinski, Fortmann, & Lezotte, 2008) while other work has not (e.g., Schneider et al., 2002). A second way in which climate strength has been examined is as moderator of the relationship between climate itself (i.e., the mean climate score) and outcomes, with the underlying assumption that higher consensus coupled with moderate to above-average-level (mean) climate would result in more positive outcomes than low consensus because of process loss (Lindell & Brandt, 2000). While several studies have supported this notion (e.g., Colquitt et al., 2002; Lindell & Brandt, 2000; González-Romá et al., 2002; Schneider et al., 2002), results are often weak. One reason for the weak results is that theoretical and mathematical relationship between the level of climate (mean) and strength of climate perceptions (variance) is nonlinear, particularly when the full-scale range is attenuated in the data, whereas most tests of moderation have used linear cross-product terms. Two exceptions (Dawson, González-Romá, Davis, & West, 2008; Dickson, Resick, & Hanges, 2006) show the importance of examining the joint effect of climate and climate strength on outcomes through nonlinear means.

A number of lingering questions remain with respect to the emergence and strength of climate. In particular,

the relative importance of the various factors (structure, homogeneity, interaction, group processes, and leadership) and the degree to which they are substitutable is largely unknown. Few studies have examined a range of antecedents of climate strength simultaneously (Lindell & Brandt, 2000, is an exception). The little work that has been done to date tends to indicate that the effects of the antecedents are additive. For example, when examined simultaneously, both leader visibility and cohesion were related to justice climate strength (Naumann & Bennett, 2000) and transformational leadership and communication network density were both significantly related to safety climate strength (Zohar & Tenne-Gazit, 2008). Other research has shown the factors have interactive effects in their relationship to climate strength, such as between transformational leadership and group cohesion (Luria, 2008). It also is likely that some factors may compensate for others. For example, to the degree that the HR system is particularly strong and salient, other factors to enhance emergence and strength may not be necessary, whereas when HR system strength is weak, leadership and interaction processes may be particularly important. Additional research is needed to determine the relative importance, interactive effects, and substitutability of the factors for strength.

Without agreement-based strength or a shared sense of the climate, linkages between organizational climate and subsequent outcomes at the aggregate level are unlikely to be realized (see Figure 24.1). Yet, the fostering of agreement-based strength does not necessarily lead to system- or alignment-based strength. Agreement-based strength can be viewed as a necessary but insufficient condition for the formation of other types of strength.

System-Based Strength

Culture and climate can be more or less intense in terms of the range of employee behaviors that are expected in order to be in accordance with the culture (e.g., Payne, 2000). System-based strength is based on the notion of a tight culture whereby deviations from norms are not tolerated as well as the pervasiveness of the organizational context in defining and limiting the expected behaviors across a wide range of behaviors (Payne, 2000). Intensive socialization programs as well as a culture that embodies strong sanctions for violating norms help to foster system-based strength (Schneider et al., 2011b). We also purport that system-based strength is fostered when a set of practices is developed that is internally consistent and intensive. Internal consistency is achieved when the set of practices reinforce and support one another around a

specific focus (e.g., Pfeffer, 2010). Intensity is achieved when a wide range of practices are implemented that pervade all aspects of organizational life. For example, high-performance HRM systems (e.g., Becker & Huselid, 1998) are based on the premise that employee involvement and participation are cornerstones of a productive workforce. This set of practices would be considered intense because it involves a wide range of practices that require a great deal of participation on the part of employees and encompass the range of organizational activities (Ostroff, 1995). Intense systems affect a large number of employees and a large number of behaviors, and are designed to induce a uniform set of behaviors among employees (Bowen & Ostroff, 2004).

Alignment-Based Strength

Alignment refers to the notion that the key attributes of an organization (e.g., strategy, goals, culture, practices, structure) must be arranged and designed in such a way that they complement one another and operate together harmoniously (e.g., Anand & Daft, 2007; Kinicki et al., 2011). In this vein, we argue for the importance of alignment between culture, practices, and climate. Practices must be designed in such a way that they reflect the cultural assumptions and values (Schein, 2010). For example, a cultural value emphasizing teamwork coupled with a reward system emphasizing individual competitive performance sends mixed messages to employees, likely resulting in confusion and frustration (Zohar & Hofmann, in press). A match between espoused values and practices can also facilitate greater agreement on climate (Dickson et al., 2006). Further, the climate that is perceived should be one that was intended through the set of practices (Zohar & Luria, 2005). The practices, policies, and procedures, when administered in a strong way (e.g., salient, consistent, fair, valid), provide the elemental content in the form of a cognitive representation of the climate, which can result in positive organizational outcomes. To the extent that the homogeneity process is strong *and* the process of administering practices is strong, similar cognitive elements should form and shared perceptions of climate should emerge that are consistent with the intent of the practices (thereby creating alignment-based strength). However, to the extent that the homogeneity process is weak, and/or practices are not administered in a way to create a strong situation, social interaction and leadership processes can lead to the formation of shared perceptions of climates that may not be consistent with the culture and what was ultimately intended (Bowen & Ostroff, 2004).

We propose that leaders play a key role in creating alignment among subunits in an organization and across individuals. Our perspective is consistent with upper-level management theory, which is based on the notion that “strategies are a product of the interaction of the individual leader and the organization’s internal and external environment. Systems thinking is required that aims to produce the synergies that are more than the sum of the individual parts of the organization” (Bass & Bass, 2008, p. 682).

Founders and strategic leaders are purported to be the architects for establishing culture in the organization and they are responsible for creating alignment between strategic goals and culture in order to facilitate maximum organizational performance (Chow & Liu, 2009; Kinicki et al., 2011; Schein, 2010). Further, the effectiveness of the HRM system relies on close communication and integration among HR professionals and top management (Lado & Wilson, 1994; Ostroff, 1995) and this close relationship is needed to ensure alignment between practices and business needs, strategy, and culture (Maxwell & Farquharson, 2008).

Moreover, leaders at all levels can serve as aligners between culture, practices, and climate. Role modeling and the visible behaviors of leaders at all levels of management communicate core cultural assumptions and values (Schein, 2010). Importantly, Simons (2002) argues that employees must perceive “behavioral integrity” in the leader, that is, a consistent pattern of alignment between a manager’s words and deeds over time, with particular attention paid to the alignment between espoused and enacted values of the leaders. Further, policies and practices that are incompatible with the espoused values are also likely to be seen as leaders’ word–deed misalignments, which can undermine credibility and trust in leaders. This relates to Schein’s (1985) argument that employees experience the organization and values more in reference to what “ought to be” rather than “what is.” Behavioral consistency can be a means to achieve alignment between the two.

The importance of behavioral consistency implies that not only do practices need to be designed in a way that aligns with cultural assumptions and values, they must also be enacted by leaders in way that reinforces this alignment. What leaders attend to, measure, and control communicates beliefs and expectations to employees (Schein, 2010). Inconsistency in doing so creates confusion and ambiguity (Schein, 2010), which can lead to the development of a climate that was not intended (Bowen & Ostroff, 2004) or to a fragmented culture (Martin, 2002). Thus, when lower

level leaders consistently monitor work in progress, provide timely communication, and enforce practices, rules, and procedures in consistent ways, they clarify supervisory directives and expectations as well as behavior–outcome contingencies for employees (Yukl, Gordon, & Taber, 2002; Zohar, 2002; Zohar & Luria, 2004).

Employees infer cause–effect attributions from communications and signals in the context to determine what behaviors are important, expected, and rewarded (Kelley, 1973; Bowen & Ostroff, 2004). It is important that leaders convey and communicate messages consistently over time and over different events in order for employees to make correct attributions about the environment because making sense of the organizational environment often entails numerous cycles of attending to information, interpreting it, acting upon it, and receiving feedback to further clarify perceptions of the organizational environment (Morgeson & Hofmann, 1999; Weick, 1995). Transformational leaders are expected to be particularly adept at this because they are able to realign employees’ norms and values around specific goals, and facilitate knowledge sharing about the organization’s cultural values, beliefs, and climate (Bass & Avolio, 1994; Hartnell & Walumbwa, 2011; Kinicki et al., 2011).

Summary

When agreement-based strength is fostered in conjunction with alignment-based strength between the climate and practices and in conjunction with system-based strength, an organizational climate emerges that is consistent with what was intended by the practices. Alignment-based strength between culture and practices and a strong system-based culture with intense practices that induce and reward uniform values and behavior is also needed. Further, leaders need to model values, enact practices, and communicate climate content consistently to enhance alignment among culture, practices, and climate. When strength and alignment are achieved across culture *and* climate, expected relationships between climate and organizational outcomes are more likely to be realized.

Subcultures and Subclimates

Subcultures and subclimates can emerge throughout the organization. Within-unit social interactions, communication, interdependencies, and different leadership processes can lead to the formation of a culture and/or climate within a group that may differ between groups in the same organization (Schneider et al., 2011b).

While some have argued that subcultures and climates can meaningfully exist when core values or perceptions

are consistent with the organizational culture and climate. This raises the question of whether in today's large, diversified, geographically dispersed organizations, there can be such a thing as a molar organizational culture and climate (Martin, 2002). Can shared meanings and perceptions develop across such an organization? As a first step, studies are needed that include multiple units from multiple organizations to determine whether units within an organization are more similar to one another than groups across organizations.

Moreover, few studies have examined the degree of consistency between units within an organization, the factors that would enhance consistency in cultures and climates across groups, and the conditions under which the existence of subclimates and subcultures is beneficial or detrimental to the organization as a whole. In the culture area, Kinicki et al. (2011) propose a multilevel system of leadership whereby senior leaders influence others across hierarchical levels of management and, through a process of compositional alignment, leaders can create horizontal and vertical alignment around the pursuit of strategic objectives across levels of management. In the climate area, aggregated perceptions across hierarchical levels within an organization were shown to be related (Griffin & Mathieu, 1997) and relationships between organizational climate and group climate have been demonstrated (Zohar & Luria, 2005). The importance of consistency in climate perceptions between employees and management was demonstrated by McKay et al. (2009) whereby financial outcomes were highest when both employees and management perceived the unit diversity climate to be positive. While these studies point to some consistency between different climates at different levels of analysis within an organization, questions remain in terms of the factors that influence this consistency. Zohar and Luria (2005) provide some initial evidence in that a greater degree of formalization and work routinization, as well as greater consensus in organizational climate, were related to smaller between-group variance in the climates in the organization. A strong HRM system with highly visible and consistent application of practices should also create greater consensus across units in climates (Bowen & Ostroff, 2004). Leaders may also play an important role in developing consistency across units in their climate. In a study of ethical leadership, the trickle-down model of leadership was examined, supporting the notion that top leaders convey the values of the organization, serve as role models, and inspire lower-level leaders to act accordingly, and in turn lower-level leaders influence unit members (Mayer, Kuenzi, Greenbaum, Bardes, & Salvador, 2009b).

To the extent that leaders play a key role as conveyers of culture and climate, the degree to which leaders at successively lower levels enact the culture and convey the climate consistently should reduce between-unit variance in climate.

At the same time, consistency across units in culture and climate may not always be necessary or desirable. While the concept of countercultures implies a negative connotation, we argue that the effect of subcultures and subclimates depends on the extent to which they are contradictory to each other or if they complement one another and potentially form a complementarity. Clearly, if two subcultures or subclimates produce negativity, conflict, politics, and negative competition between groups, the subcultures are not complementary or compatible and may be detrimental to both individual responses and organizational outcomes. However, subcultures and subclimates can exist simultaneously without creating conflict (Hartnell et al., 2011; O. Jones, 2000). For example, an innovation-based climate in one division may complement a quality-based climate in another division. If the organization's strategy is to provide high-quality service or products, but at the same time it also wants to explore entry into new markets, these two different climates may exist simultaneously in different divisions and yet produce a complementarity at the organizational level. Again, this implies that patterns across multiple cultures or climates should be investigated and that different patterns of climates may be equifinal for organizational effectiveness (Hartnell et al., 2011; Schulte et al., 2009).

CULTURE AND CLIMATE CHANGE

Interest in culture and climate change continues to grow because of organizations' responses to forces of change associated with labor market demographics, technological advancements, shareholder, customer, and market changes, social and political pressures, and human resource problems/practices (Schneider et al., 2011b). We propose that efforts to change culture necessitate a change in climate and both should be considered simultaneously. The need for culture and climate change is precipitated by several factors. Maitlis and Lawrence (2007) and Schein (2010) suggest that unit or organizational performance discrepancies are likely to signal the need for change. Different types of misalignment also signal the need for change. For example, the set of human resource practices might be inconsistent with the organization's strategy,

desired culture, or climate (e.g., Garrow & Hirsh, 2008). Similarly, an organization's culture may be incongruent with its strategies and goals (Chow & Liu, 2009) or the leadership style of senior-level executives (Kinicki et al., 2011). Change may also be needed because subcultures exist that conflict with an organization's espoused values (Lucas & Kline, 2008).

Culture Change

Several models of culture and climate change have been proffered, beginning with Lewin's (1951) unfreezing to moving to freezing perspective. Others have suggested systems models of change (Young, 2010), stage models (Kotter, 1996; Latta, 2009), and structured approaches that rely on a host of organizational development techniques (Martins, 2011). Despite the variety of proposed models for culture and climate change, the lack of research regarding the veracity of these models led to the conclusion that "an established process that can be used to manage culture change remains elusive and represents an important area in need of further research" (Martins, 2011, p. 707).

Leaders play a key role in macro-culture change. For example, Hartmann and Khademian (2010) highlight the need for leaders to create a vision and roadmap for culture change and then to use both intrinsic and extrinsic motivators to reinforce change. Marshall and Adamic (2010) and Jacobs (2010) also discuss how leaders can use storytelling to start and reinforce culture change. Further, Hatch (2000) purports that leaders serve as artifacts and, based on their actions, are used by members to derive meaning and make sense of the change. Leaders can create and reinforce culture change by using the regulatory behaviors discussed by Hartnell and Kinicki (2011) or the embedding techniques proposed by Schein (2010). Finally, culture change can be fostered by the infusion of outsiders (i.e., selecting new employees; Harrison & Corley, 2011; Schein, 2010), particularly the hiring of senior-level executives. The process of culture change can take years (Schroeder, 2010) and leaders must attend to reducing resistance to culture change (Kotter, 1996). Rigorous research supporting the viability of culture change is needed.

The role of climate as a means to facilitate culture change has not been directly addressed. We believe that culture change starts not only with a change, in traditionally discussed artifacts like stories and espoused values, but also with a fundamental change in an organization's policies, practices, and procedures.

Climate Change

Climate is formed from the practices, policies, and procedures of the organization. Thus, a change in practices should result in a change in the content of climate (Kopelman, Brief, & Guzzo, 1990) and force a reevaluation of the situation (Guzzo & Noonan, 1994). The employee is deemed to be a "receiver" of the communicative content of practices and procedures (Guzzo & Noonan, 1994; Rousseau, 1995). Changes in practices and communications are likely to trigger systematic processing as employees derive conscious explanations of the information, that is engage in sense making (Guzzo & Noonan, 1994). Changes in particular practices (e.g., a change from a merit-based system to profit sharing, or adding a new practice such as teams) are expected to evoke a process of reinterpreting what the organization expects. Unfortunately, little research has explicitly tested whether climates change in reaction to a change in practices, and no research that we are aware of has explicitly examined the process of *how* climate perceptions change over time.

Moreover, constructs may shift levels over time (Dansereau, Yammarino, & Kohles, 1999; Yammarino & Dansereau, 2011). Changes in the set of practices may initially cause discord and disagreement among individuals in an organization. Hence a previously homogeneous group with shared perceptions of unit climate may lose their "agreement" with a change in practices, thereby enabling only a focus on psychological climates. At this point, a series of event cycles ensues (Morgeson & Hofmann, 1999). Through successive interactions with one another, communications from the leader, visibility of the leader, and role modeling by the leader (Schein, 2010), over time, consensus forms and a new climate can emerge. For example, leaders who received training to emphasize safety as a priority increased interactions with employees about safety over time, resulting in significant and stable changes in safety climate and safety outcomes (Zohar, 2002). In addition, a change in practices may not produce the desired change in the climate content unless the process of the changed practices is delivered in an effective manner, for example, evoke salience, understandability, visibility, and so forth (Bowen & Ostroff, 2004).

Successful climate change may also spur reinterpretations of culture. As Zohar and Hofmann (in press) propose, climate represents shared assessments of the enacted, not just espoused, values and priorities and climate is used to decipher the deeper layers of culture. Climate perceptions become a way to socially verify the pattern of organizational artifacts, and the combined

meaning of these patterned artifacts allows for mapping relationships between observable artifacts and deep layers of culture.

CONCLUSIONS AND FUTURE DIRECTIONS

Culture and climate are similar and interrelated in that they both focus on the creation and impact of social contexts, yet maintaining a distinction between them is important if we are to understand different aspects of the social context and shared meaning and perceptions that develop in organizational life. Researchers, theorists, and practitioners are urged to more carefully attend to whether they are referring to climate or culture and to whether they are referring to idiosyncratic psychological perceptions or higher-level emergent constructs of culture and climate in an effort to help to continue to reduce confusion between the two constructs at different levels of analysis. At the same time, we argue that there is much to be learned by examining the two streams of research simultaneously rather than approaching each as separate bodies of literature. This is particularly important in light of our focus on the alignment between culture and climate.

We first highlighted how structure, practices, policies, and procedures are the mechanisms that link culture to climate, with particular attention to the notion that practices that are inconsistent with cultural values, or delivered in a weak way, may result in a climate that was unintended or inconsistent with the culture. To date, very little research has investigated the role of structural variables and human resource practices as linking mechanisms.

In addition, throughout the chapter, we emphasized how leaders influence both climate and culture in interesting ways. Leaders, through their role-modeling, behaviors, and interactions with members, serve as sense making agents for newcomers and organizational members, helping them understand and internalize the culture. Leaders also enact the practices through their behaviors, enforcement of practices, policies, and procedures, and communications and interactions with employees, helping to foster the content of climate as well as emergence and degree of consensus in climate perceptions. Leaders can also create fractions, subcultures, or subclimates when they idiosyncratically interpret and communicate the culture and climate and convey this to group members. Given the key role of leaders in the content and emergence of both culture and climate, we propose they are particularly important as aligners of culture and climate. However, research on the role of leadership in culture and

climate has been fractionalized and segmented and we encourage greater integration in future theory research to elucidate the concurrent role leaders play in both culture and climate.

Some of the reasons for the separation and difference in emphasis in culture and climate work is likely due to measurement techniques that have dominated these research areas. Climate's tradition of survey research is deductive and requires that content of climate be specified a priori, while culture's tradition of observational techniques, qualitative studies, and case studies is more inductive and allows for a deep understanding of the embedding process of cultural properties but not for robust comparisons to other organizations (Ashkanasy, Wilderom, & Peterson, 2000b). In recent years, culture research has moved toward more quantitative methods but often uses customized measures containing limited evidence of validity. We suspect that the use of ad-hoc measures is partially due to the argument that culture represents specific properties of an organization (Schein, 2010) that can be difficult to imitate (Barney, 1991), thereby necessitating the use of customized measures (Sackman, 2011). This limits generalizability. In contrast, climate researchers have typically used more standard measures with known reliability and validity, but in recent years, researchers have begun to use more customized measures to better reflect the unique aspects of the climate in the organization (e.g., Schulte et al., 2009; Tsai, 2001). Schneider and his colleagues (Schneider et al., 2011a) propose integrating both culture items (e.g., telling stories that highlight value of safety) and climate items (e.g., safe behaviors are expected and rewarded) in survey research. Finding the appropriate balance between sufficient standardization to enhance generalizability but sufficient customization to make the measures more relevant to the particular organization will be a challenge for researchers in upcoming years.

Ten years ago, relatively few of the linkages in Figure 24.1 had been tested. Research on climate and culture has burgeoned in recent years. While it is unreasonable to expect a test of the full model in any one study, across studies, most of the linkages have been supported. That said, there are still lingering research questions, particularly in the link between culture and climate, emergence, and the change process. Research on emergence and strength of climate has been growing recently, but additional multilevel research is needed to further explicate the mechanisms of emergence and strength, and the degree to which emergence factors (e.g., structure, homogeneity, interactions, leadership) are additive, substitutable, or interactive. In terms of culture emergence,

little theory and research have been developed and more work is needed in this area to explore *how* these constructs emerge. Additional research is needed to determine how alignment-based strength is fostered as well as its relationship to agreement-based and system-based strength in the emergence and impact of culture and climate.

Finally, there is a lack of longitudinal research in culture and climate change as well as reciprocal relationships among constructs and across levels. For example, organizational outcomes can have a reciprocal relationship with climate (Schneider, White, & Paul, 1998). Research is needed to determine how the feedback loops contained in Figure 24.1 operate to more fully understand relationships among culture, climate, and effective functioning of organizations over time.

DIVERSITY IN ORGANIZATIONS

The nearly 10 years following Alderfer and Sims's (2003) *Handbook of Psychology* chapter on workforce diversity have produced a bounty of research on diversity-related issues in organizations. In fact, a cursory search for diversity-related articles published in just eight of the most influential organizational journals (i.e., *Journal of Academy of Management*, *Academy of Management Review*, *Journal of Applied Psychology*, *Organizational Behavior and Human Decision Processes*, *Journal of Management*, *Journal of Vocational Behavior*, *Personnel Psychology*) from 2003 to the present reveals more than 250 articles. In the current chapter, we attempt to summarize and highlight several key themes and contributions of this burgeoning body of diversity research.

To do this, we first begin by defining some of the most basic constructs needed to understand the diversity literature. Such a discussion also includes a consideration of the benefits and challenges to conducting diversity-related research. Second, we attempt to update Alderfer and Sim's chapter by describing how the past 8 years of research has been guided by some of the theories that Alderfer and Sim's earlier outlined. We also add to this review some of the new theoretical insights that have guided or seem very likely to guide future diversity-related research. Third, we pose four research questions related to diversity that we believe address particularly salient and hot topics that have been the focus of a good deal of recent organizational research on diversity. For each of these issues, we not only describe the state of research and what has been done,

but we also make recommendations for future research on these four topics. Finally, we draw some conclusions about the literature and make some more general speculations about how researchers might advance our theoretical knowledge and practical applications of organizational diversity in the years to come.

Basic Concepts and Issues in Studying Diversity in Organizations

Continued and dramatic projections in the growth of diversity in the U.S. workforce and beyond are ubiquitous (see Toossi, 2002). But what is meant by the construct of "diversity" itself? How do we measure it? And what are the benefits and drawbacks to diversity within organizational settings? We begin our chapter by reviewing definitional and other very basic issues influencing diversity research. Many of these issues—even basic definitional ones—can become contentious, so we begin by informing the reader of some basic diversity-related concepts, challenges, and controversies in examining diversity in organizations.

Definitions of Diversity

When most people think about diversity, they typically think first and foremost about race and then gender-related issues. In fact, the Merriam Webster dictionary defines *diversity* as "the inclusion of different types of people (as people of different races or cultures) in a group or organization." Others begin with a much more inclusive approach to defining diversity and include, in their definitions of diversity, the inclusion of, tolerance of, and/or respect for

others based on variations in age, attitudes and values, ethnicity, gender, physical abilities, educational background, personality, political beliefs, race, religious beliefs, sexual orientation, socioeconomic status, tenure, and weight (e.g., Harrison, Price, Gavin, & Florey, 2002; University of Oregon, 2011; Williams & O'Reilly, 1998).

Definitions of diversity are not without points of debate. One such debate involves the legitimacy of even including, tolerating, or respecting certain types of diversity. For instance, many people blatantly oppose variations from heterosexuality and it is legal in many contexts to discriminate on the basis of sexual orientation and encourage such discrimination at an institutional level. Another argument focuses on the fact that not all groups are valued equally for their diversity and inter- and intra-differences in these valuations often emerge (Avery & Johnson, 2007; Hernandez, 2007; Schaerer, 2010). For instance, the Model Minority Phenomenon suggests that being Asian counts for little when considering the diversity of an organization because Asian Americans are too successful to be characterized as disadvantaged (see Cheng, 1997). Moreover, people debate whether the call for increased racial diversity within U.S. organizations can be achieved successfully by importing racially diverse immigrants. Addressing the need for diversity in academia, Tapia (2007) argues that "true diversity doesn't come from abroad" and that the creation of diversity in academies should have little to do with hiring international scholars.

To categorize diversity in meaningful ways, researchers have distinguished between surface- versus deep-level diversity (see Harrison, Price, & Bell, 1998; Milliken & Martins, 1996; see also de Chermont, 2003; 2008). Surface-level characteristics are those that are quickly apparent to interactants, such as race, gender, and age. These characteristics also are generally unchangeable and measured in very easy, accurate ways. Deep-level characteristics are those that take time to emerge in interactions, such as attitudes, opinions, and values. These characteristics tend to be more mutable, and are measured through verbal and nonverbal behavioral patterns. It is important to note that surface- and deep-level characteristics are not necessarily congruent and may result, instead, in collisions or incongruencies; that is, two Hispanic men may have very different attitudes on political issues (see Phillips & Loyd, 2006). Moreover, people who look very different on surface characteristics (i.e., a man and a woman) may hold very congruent deep-level characteristics (i.e., values about equality or about politics).

For the purpose of the current chapter, we mostly discuss diversity in terms of surface-level characteristics and

summarize the research that has been done on differing dimensions of age, ethnicity, gender, height, physical disabilities, race, religious beliefs, sexual orientation, and weight. We are not trying to be exclusive of any additional feature and believe that our theoretical discussions and research questions have implications for all forms, whether surface or deep, of diversity.

Beyond the type of diversity, there are a number of issues concerning how diversity should be measured. For instance, a researcher interested in gender diversity could use the proportion of men or women in the unit, Blau's index of heterogeneity, or the average Euclidean distance on gender for members of the work unit (Williams & Mean, 2004). This diversity in ways of conceptualizing diversity recently led Harrison and Klein (2007) to consider the implications of scholars' decisions concerning the choice of measurement. They determined that diversity measures can take one of three forms: separation, variety, or disparity. Separation pertains to the average distance between group members on a given characteristic and is typically measured using the standard deviation for continuous variables (e.g., age) and average Euclidean distance for categorical variables (e.g., race). Variety captures the quantity of different categories of a characteristic represented within a group and is most commonly represented with Blau's index of heterogeneity. Disparity looks at inequality of a distribution and has rarely been examined in the diversity literature. Though we often discuss research employing variety or separation approaches interchangeably, or without explicitly acknowledging the particular approach utilized, it is important to recognize that the type of measurement can have important theoretical and empirical consequences (Bell, Villado, Lukasik, Belau, & Briggs, in press; Harrison & Klein, 2007).

Need for Methodological Diversity

After a researcher has determined what type of diversity to study and how to conceptualize it, another important decision involves how to best address and answer the research question. As one might expect from scholars of diversity, the literature contains considerable variety in the samples and settings utilized to test their theories and hypotheses about diversity and its effects. That said, there is a rather significant range restriction concerning the methodologies employed within these studies. Most studies employ survey data that are often self-report in nature. In fact, we could find only two qualitative studies on diversity (Gibson & Gibbs, 2006; Roberson & Stevens, 2006) appearing in the outlets we reviewed over the

past 8 years. Moreover, the number of simulation studies focusing on diversity was not much greater (Allen, Stanley, Williams, & Ross, 2007; Finch, Edwards, & Wallace, 2009; Newman & Lyon, 2009; Roth, Bobko, & Switzer, 2006; Tonidandel, Avery, Bucholtz, & McKay, 2008). To provide some context, contrast this with the fact that there were *at least* 10 diversity meta-analyses published during this period.

One benefit of methodological diversity is that it allows for better triangulation, which simply means that studying phenomena of interest from multiple perspectives helps to provide a more comprehensive understanding (Jick, 1979; see also Leslie, King, Bradley, & Hebl, 2008). If the conclusions drawn from the differing methods converge, the field can have greater confidence in the validity of those results and view the relationships of interest as relatively robust. What is perhaps more intriguing, however, is when conclusions drawn from differing methodologies diverge (see Hebl & Dovidio, 2005). In such instances, the conflicting findings highlight needs for future research and often indicate that seemingly straightforward processes are more complex than they might appear.

Only a few recent diversity articles appearing in the top outlets have employed the strategy of triangulation by combining multiple studies involving differing, yet complementary, methodologies. For instance, Gibson and Gibbs (2006) utilized interviews (study 1) and team-level survey data (study 2) to shed light on how virtual work arrangements, which included nationality diversity, influence team innovation. Hebl, King, Glick, Singletary, and Kazama (2007) conducted a field study as well as a laboratory experiment to show how pregnant customers and job applicants are treated. The results suggest a system of complementary rewards and punishments that discourage women from pursuing work (gender incongruent) but encourage them to shop (gender congruent). Subsequently, Johnson, Murphy, Zewdie, and Reichard (2008) examined people's cognitive associations between gender and leadership using survey, experimental, and qualitative data. Their results produced several informative conclusions regarding differences in the ways that men and women view leadership in general and male and female leaders in particular. In another example, Leslie and Gelfand (2008) combined a lab experiment and field data to determine that individuals are more likely to handle a discrimination claim within their organization if they perceive the company's diversity climate favorably. Moreover, King and Ahmad (2010) also combined lab and field study data to show that Muslim job applicants face challenges when they seek employment. Unfortunately, however, it is clear

that these studies are more the exception than the norm within the literature.

We strongly encourage diversity researchers to employ atypical methodological strategies to provide greater triangulation within the literature. For instance, simulation studies can prove quite useful in developing or refining constructs to measure diversity or related constructs within groups (Martell, Lane, & Emrich, 1996; Tonidandel et al., 2008). Such studies also adeptly illustrate how commonly employed human resource practices might impact the level of diversity within an organization (Finch et al., 2009; Newman & Lyon, 2009; Roth et al., 2006). Alternative sampling strategies may prove necessary when studying traditionally underrepresented populations (e.g., disabled employees). In fact, researchers often need to oversample members of these groups, relative to their proportion in the population, to obtain sufficient power for comparative analysis investigating majority–minority differences. Moreover, snowball sampling (i.e., referral-based sampling) may be the only reasonable method in some instances for obtaining sufficiently large samples for statistical significance testing of certain populations that are hard to reach or even identify (e.g., gay, lesbian, transgendered, or biracial employees).

In accordance with encouraging researchers to be creative in designing their methodologies, we also implore editors and reviewers to be more receptive of nontraditional strategies. It is unrealistic to expect conventional methods that were designed to study a relatively narrow subset of the total working population (i.e., young, Christian, straight, White men) to prove equally effective in studying relatively neglected subsets of the broader population. Nevertheless, there are often biases in the publication process against research perceived to be nonconformist, particularly with respect to diversity (see Cox, 2004, for an excellent discussion of this topic). Thus, we urge those involved in the peer review process to consider projects on a case-by-case basis, paying particular attention to whether a particular methodology is appropriate in the given context (as opposed to whether they deem it a practical approach for conducting research in general). It is likely that the prospective costs associated with a particular method often will be outweighed by the insight the findings provide in filling a gap in the literature.

Benefits and Drawbacks of Diversity

Having defined what it is, how it should be measured, and how it should be studied, it is important to briefly review why it is valuable to conduct research on diversity in the first place. For more than half a century, scholars

have studied the effects of diversity in teams and organizations. Despite the considerable volume of this literature, however, reviews (e.g., van Knippenberg & Schippers, 2007; Williams & O'Reilly, 1998) paint mostly a muddled picture riddled with positive, negative, and null effects. For instance, some research ties diversity to negative outcomes such as poorer communication, more negative attitudes, and greater conflict and withdrawal. Ostensibly, this occurs for two reasons. First, demographic differences may coincide with deeper level differences (e.g., attitudes, values, and beliefs) that lead people to disagree fundamentally, thereby promoting conflict. Second, demographic differences often enhance uncertainty about others, thereby making it more difficult to anticipate and interpret interpersonal communicative messages (for reviews, see Dovidio, Hebl, Richeson, & Shelton, 2006; Hebl et al., 2008).

On a more positive note, other studies illustrate potential benefits of diversity such as heightened creativity and decision making (van Knippenberg & Schippers, 2007). Such outcomes may be particularly okay when diversity in appearance coincides with diversity in perspective. Greater breadth of perspectives provides more range in the types of possible solutions generated when attempting to solve problems (i.e., greater creativity). In turn, having a broader array of implementable ideas may facilitate groups and organizations in arriving at higher quality decisions. Thus, it appears that diversity may hurt or hinder performance depending upon how it influences interpersonal dynamics within the unit.

Beyond these more direct ways that diversity influences group and organizational outcomes, there are more indirect associations as well. For instance, some individuals believe that organizations have a moral obligation not to discriminate on the basis of any non-job-related characteristics (Demuijnck, 2009). Though the pervasiveness of this belief is debatable, it appears that there are enough people, or enough of the right people, holding this viewpoint to influence key organizational outcomes. In fact, companies caught engaging in discrimination tend to experience declines in their stock price, whereas those receiving diversity commendation enjoy the opposite (Roberson & Park, 2007; Wright, Ferris, Hiller, & Kroll, 1995). The perceived premium for appearing diverse is so high that it often leads diverse organizations to flaunt it and those that are not to fake it (Bernardi, Bean, & Weippert, 2002; Conklin, 2001). Hence, it is clear that diversity can impact key organizational outcomes, which makes it an important topic to understand. Accordingly, we now turn our attention to the predominant theories in the diversity literature.

DEFINING THEORIES THAT GUIDE DIVERSITY RESEARCH

One of the most significant contributions of Alderfer and Sims (2003) is the identification and discussion of theories that guide diversity research. In this chapter, we update their discussion of these theories and/or replace some of them with others we have found particularly useful or promising. The exclusion of earlier theories does not necessarily indicate that they are not still informing or guiding research; however, we simply do not have the space to cover each and every theory. Thus, we have chosen those we believe to be particularly informative, and these include: social identity theory, relational demography, categorization elaboration model, stigma theory, stereotype content model, lack-of-fit model, and social role theory. For each of these, we summarize the theory and add a discussion of the relevant research published since the appearance of Alderfer and Sims's chapter. We also discuss potential avenues for future research that we believe may be particularly compelling and fruitful.

Social Identity Theory

According to social identity theory (SIT; Tajfel & Turner, 1985), individuals classify themselves and those they encounter on the basis of readily identifiable characteristics such as racioethnicity, sex, or age. The purpose of these classifications is to determine whether others belong to one's in-group (similar) or out-group (dissimilar). Because (a) individuals are motivated to feel positively about themselves and (b) the in-group is seen as an extension of the self, there is an inherent inclination to see the in-group in a favorable light. This tendency often results in forms of perceptual distortion wherein in-group member positives or out-group member negatives are exaggerated, which are known as favoritism and denigration, respectively.

Within organizations, one of the key issues relating to the theory pertains to the relative strength of an individual's multiple identities (Ashforth & Mael, 1989). People belong to any number of groups and membership in some groups will be more important to their self-concept than their membership in others. For instance, an employee simultaneously could be Hispanic, female, disabled, Catholic, and belong to a particular functional department and project team within the organization. These various identities can create competing priorities if efforts to affirm one's identity come at the potential expense of

another (e.g., working for an organization that discriminates against women). Thus, organizations commonly seek to maximize employees' identification with the organization, thereby ensuring that affective commitment and all of its positive consequences are optimized.

Diversity researchers have employed SIT as a theoretical mechanism to help explain several organizational processes. For instance, recent scholarship (e.g., Homan et al., 2008; Shteynberg, Leslie, Knight, & Mayer, 2010; Swann, Polzer, Seyle, & Ko, 2004) suggests individuals may either support or oppose organizational diversity or policies associated with it, such as affirmative action, depending on whether they see them as consistent or inconsistent with their salient group identities. Within work groups, both individuals and their groups perform better when members recognize and confirm one another's valued social identities (Milton & Westphal, 2005; Swann et al., 2004; Thatcher & Greer, 2008). Likewise, recruitment researchers (e.g., Avery, 2003; Avery & McKay, 2006; Kim & Gelfand, 2003; McKay & Avery, 2006; Umphress, Smith-Crowe, Brief, Dietz, & Baskerville Watkins, 2007; Walker, Feild, Giles, Armenakis, & Bernerth, 2009) have shown that job applicants actively look for information signaling to them that a company's environment is likely to affirm their relevant social identities when pursuing employment opportunities. Thus, SIT has proven quite useful in helping researchers understand the effects of diversity in organizational settings.

Despite its utility in this regard, scholars continue to look for interesting ways of expanding SIT to make it more comprehensive in explaining diversity-related phenomena. One prime example of this type of extension involves the consideration of how individuals actively manage their multiple important identities simultaneously (Chattopadhyay, Tluchowska, & George, 2004; Hewlin, 2003, 2009; Roberts, 2005). For instance, what happens if an environment affirms one important identity while simultaneously threatening another? Another interesting example involves less readily detectable social identity markers such as religion or sexual orientation. Given that identity confirmation is beneficial to employees, but disclosure could result in discriminatory treatment, individuals with invisible identities face somewhat of a conundrum concerning whether to disclose this information. Some very interesting theoretical and empirical coverage (e.g., Clair, Beatty, & MacLean, 2005; Phillips, Rothbard, & Dumas, 2009; Ragins, Singh, & Cornwell, 2007) has examined the implications and limitations of SIT in these types of situations, fleshing out the nuances associated with the disclosure dilemma.

Relational Demography

In the late 1980s, Tsui and O'Reilly (1989) developed a theoretical framework that incorporated and extended some of the tenets of SIT to integrate two streams of related work that were developing independently of one another. On the one hand, demography researchers focused on explaining how an organization's composition could influence individual and organizational behavior. On the other, more micro-diversity researchers devoted their attention to assessing how individual demographic characteristics influence people's organizational experiences. Relational demography sought to combine these two streams in the form of a person-situation interaction perspective. The basic notion entailed a contingency approach wherein the independent influence of a unit's demography and an individual's demographics were dependent on one another, with greater similarity between the two yielding more favorable outcomes.

Relational demography was initially proposed at the dyadic level of analysis and research continues to explore how supervisor-subordinate or rater-ratee similarity influences outcomes (e.g., McFarland, Ryan, Sacco, & Kriska, 2004; Sacco, Scheu, Ryan, & Schmitt, 2003; Shore, Cleveland, & Goldberg, 2003; Stauffer & Buckley, 2005). Nevertheless, scholars have extended the framework in a number of interesting ways. Evidence suggests that employees are less likely to perceive discriminatory treatment and more likely to feel supported when they are more demographically similar to their coworkers and supervisors (Avery, McKay, & Wilson, 2008; Bacharach, Bamberger, & Vashdi, 2005). Similarly, mistreatment in the form of demographic differences in pay disfavoring women and minorities tend to be smaller in units containing greater proportions of women and minorities, respectively (Joshi, Liao, & Jackson, 2006). These findings imply that employees often perceive more favorable treatment as the proportion of similar others in their surroundings increases, which could help to explain why individuals tend to identify more with and be less prone to leave groups containing greater proportions of in-group members (Chattopadhyay, George, & Lawrence, 2004; Hom, Roberson, & Ellis, 2008; Sacco & Schmitt, 2005).

One of the most promising recent extensions to relational demography involves the identification of boundary conditions to the effects of similarity in organizations. Essentially, if it is known that dissimilarity often proves detrimental to employees, it is especially important to ascertain what contextual characteristics heighten or diminish this occurrence. Along these lines, recent studies

have produced several key insights. For instance, organizational climate and culture appear to play a key role, as demographic dissimilarity's impact is less pronounced when organizational cultures emphasize collectivism or climates accentuate collegiality or support for diversity (Avery, McKay, Wilson, & Tonidandel, 2007; Bacharach et al., 2005; Chatman & Spataro, 2005; Gonzalez & DeNisi, 2009). Beyond the organization, an individual's residential context also appears pertinent as dissimilarity in one's neighborhood influences reactions to dissimilarity at work (Avery et al., 2008; Brief, Umphress, Dietz, Burrows, Butz, & Scholten, 2005). Moderators are also surfacing at the individual level (e.g., Stewart & Garcia-Prieto, 2008). Most notably, scholars continue to examine asymmetry within relational demography by exploring differences between majority and minority group member responses to demographic dissimilarity (Avery et al., 2007; Chatman, Boisnier, Spataro, Anderson, & Berdahl, 2008; Chatman & O'Reilly, 2004; Tonidandel et al., 2008). Additionally, evidence indicates that identity enhancement motives trump in-group favoritism when the two conflict, as similarity may not be viewed favorably if the similar others are perceived to reflect poorly on the in-group (Avery et al., 2007; Lewis & Sherman, 2003).

Categorization–Elaboration Model

A more recent theoretical model, introduced by van Knippenberg, De Dreu, and Homan (2004), attempts to clarify the mediating mechanism between group-level diversity and performance. They purported that one reason diversity potentially enhances group functioning is that differences in identity often correspond to differences in perspectives. Based on this logic, heterogeneity within a team should enhance its access to a broader array of information. This information, in turn, should help to facilitate creativity and decision making, thereby increasing the team's productivity. Unfortunately, this process describes the ideal manner in which a team might function and their model suggests that the key to unlocking diversity's potential lies in helping groups ensure that the exchange of information between group members is as unencumbered as possible (see van Knippenberg & van Ginkel, 2010 for a more comprehensive discussion of the theory). As the preceding description suggests, the moderators of the diversity–information elaboration linkage are critical. Although the combination of moderation and mediation they proposed in their model was quite complex, one critical implication is that numerous contextual factors may help to determine whether diversity facilitates or impedes information elaboration.

Following the theory's introduction, several studies have identified variables influencing the amount of information elaboration that takes place within diverse teams. For instance, the presence of greater transformational leadership appears to enhance the favorability of the diversity–performance relationship by increasing the amount of elaboration within the group (Kearney & Gebert, 2009). Among group members themselves, it seems that characteristics such as diversity beliefs (i.e., inclinations regarding whether diversity helps or hinders groups), openness to experience, and need for cognition are important (Homan et al., 2008; Homan, van Knippenberg, Van Kleef, & De Dreu, 2007; Kearney, Gebert, & Voelpel, 2009). Specifically, diverse workgroups are better equipped to perform well when their members see diversity as a potential benefit, are receptive to new things, and are highly motivated to understand things they encounter.

In one particularly interesting study, Dahlin, Weingart, and Hinds (2005) tested some tenets of the information elaboration model in examining the linkage between team diversity (educational and national) and information usage. Specifically, they posited that diversity would influence the range, depth, and integration of information used by the group. Range pertains to the quantity of knowledge categories presented within the group (i.e., how many different things do they use?). Depth refers to the differentiation among the knowledge categories represented (i.e., how different from one another are the things they use?). Integration captures the extent to which the different knowledge sources are linked (i.e., how well do their different things fit together?). Their findings indicated that both types of diversity helped to increase information use, with moderate levels (relationships were inverted U-shaped curves) of educational and national diversity corresponding to the most range and depth. Nevertheless, integration was lowest when educational diversity was high and national diversity was moderate. Based on these findings, the authors concluded that “both types of diversity provided information-processing benefits that outweighed the limitations associated with social categorization processes” (p. 1107). Thus, it appears that most of the research investigating the elaboration model has proven fairly supportive. This suggests future research should continue to examine the ways that diversity influences the distribution and utilization of information in groups.

Stigma Theory

Widely recognized at the forefront of stigma theory is Goffman (1963), who defined *stigma* as socially

constructed marks that deeply discredit, taint, and discount individuals. In his classic book, Goffman describes with very rich, poignant first-person accounts the social interactions that mar the lives of many different types of stigmatized individuals (e.g., epileptics, stutterers, racial minorities). Goffman differentiated three categories of stigmas: aberrations of the body (e.g., physical disability, birthmarks), characterological flaws (e.g., drug addictions, mental illnesses), and “tribal stigmas” (e.g., ethnicity, nationalities, religious backgrounds). Not surprisingly, characteristics of diversity often serve as stigmas and cue the process of stigmatization—or stereotyping, prejudice, and discrimination. Consistent with this, sociologists Link and Phelan (2001) proposed in their definition of stigma theory that stigmatization occurs when five components converge. First, individuals label others based on salient cues. Second, the labeled differences get linked with stereotypes. Third, groups of individuals are separated into those who have the labeled differences (“they”) and those who do not (“we”); (see also Allport, 1954). Fourth, emotional reactions are directed between these two groups of individuals. And fifth, status loss and discrimination occurs with those who are set apart as different.

Stigma theory consistently highlights the dynamic nature and how the process of what gets valued is negotiated within social interactions and social norms (Goffman, 1963; Jones et al., 1984). Thus, what is conceptualized as a stigma in one interaction could be viewed as an asset in another. Similarly, certain stigmas (e.g., homosexuality) may be activated in one setting (e.g., a fundamentalist church meeting) but not in another (a modern art show), and some physical environments (e.g., buildings without elevators) may increase the salience of a stigma (e.g., certain physical disabilities) in ways that other environments do not. The impact of a potential stigmatizing “mark” also is influenced substantially by personal, social, and cultural values (see Chao & Moon, 2005; Umphress, Simmons, Boswell, & Triana, 2008).

While all people experience limitations in certain contexts, Crocker, Major, and Steele (1998) suggest that stigmatized individuals are those individuals who experience stigmatization across a wide variety of social contexts. Such experiences are evident in the workplace, too, and recent organizational literature has compiled many studies indicating that diverse targets face workplace stereotypes (e.g., Heilman & Okimoto, 2007) and organizational discrimination (e.g., Judge & Cable, 2011; Madera, Hebl, & Martin, 2009) and that targets’ organizational-related behaviors can be negatively affected through this discrimination (e.g., Brown & Day, 2006; Gupta, Turban, &

Bhawe, 2008; Nguyen & Ryan, 2008; Shapiro, King, & Quinones, 2007; Singletary, 2009).

A great deal of research has been done on the perspective of the perceiver and the stigmatized target; however, the majority of this research focuses on attitudes and prejudice rather than discriminatory behaviors (see Fiske, 1998). To more completely understand the complexity of stigma, it is critical to understand both perceiver and stigmatized target together in actual behavioral interactions, and we promote future research that does this and looks at behaviors (see Hebl & Dovidio, 2005; Hebl et al., 2008). We also promote future research that more clearly links what the short- and long-term workplace implications are for those who experience repeated stigmatizing interactions. One recent topic that has emerged in the workplace literature is the notion that stigmas can influence not only targets but associates (i.e., coworkers, friends) of the targets as well (see Kulik, Bainbridge, & Cregan, 2008; Hebl & Mannix, 2003). The implications of carrying a courtesy stigma or being an ally in the workplace are prime areas for research. Finally, future stigma research might also investigate how stigmas play out on the Internet and/or in virtual interactions, which have been significantly proliferated due to the rise in social media (e.g., Facebook) that allows employers greater access to personal information about prospective and incumbent personnel.

Stereotype Content Theory

At the foundation of the stigma construct are stereotypes, which have experienced significant theoretical development of their own. As described by the authors of the stereotype content model (Cuddy et al., 2009), psychology researchers have long noted that (a) humans have a need to belong (see Baumeister & Leary, 1995) and (b) there exist in almost every culture hierarchical differences in structure and competition for resources. From this, we note the strong need people have to respond to others on two basic dimensions that are aligned, socially desirable traits: warmth and competence (Cuddy, Fiske, & Glick, 2008). The first dimension (i.e., warmth) allows perceivers to accurately assess whether targets are “friends versus enemies” and the second (i.e., competence) allows targets to judge whether “they can effectively achieve things.” Cuddy and colleagues (Cuddy et al., 2009; Cuddy, Fiske, & Glick, 2007; Fiske, Cuddy, Glick, & Xu, 2002; Fiske, Xu, Cuddy, & Glick, 1999) suggest that the two dimensions are orthogonal and can be placed on two continua to create four different categories. Thus, individuals can perceive targets to be low on both dimensions (e.g., the poor, homeless), high on both dimensions (e.g., the middle

class, Whites), high on competence but low on the warmth dimension (e.g., Asians, men), and low on competence but high on the warmth dimension (e.g., elderly, disabled). Reactions to those with mixed endpoints tend to be ambivalent.

Importantly, Fiske and colleagues suggest that a group's position within the two continua greatly influences resulting social structural variables. Those who are perceived to be in high- (versus low-) status groups tend to be imbued with more competence. In addition, those perceived to be in competition with one's own group are often associated with low warmth and low levels of liking. Where the particular stereotype falls along both of these dimensions (i.e., warmth and competence) is often associated with specific sets of emotional reactions such as prejudice, admiration, contempt, envy, and/or pity. The stereotype content model, therefore, is a theory that allows researchers to make predictions about responses to certain types of people. For instance, people may typically feel pity toward physically disabled and elderly individuals but feel envious prejudice toward White men and Asians (Lin, Kwan, Cheung, & Fiske, 2005).

The body of research elucidating the cross-cultural similarities predicted and found from the stereotype content model is impressive and is beginning to guide theory development and explain social and structural inequities within organizations as well as societies. For instance, recent research has shown how immigrants may be characterized as something between an in-group and out-group, but that this differs according to type of nationality, race, ethnicity, and class (Lee & Fiske, 2006). Such results may reveal why model minorities (i.e., Asians) often are judged more favorably than low-status clusters (i.e., Latinos, Mexicans, Africans), even when their credentials are exactly the same (King & Ahmad, 2010; King, Madera, Hebl, Knight, & Mendoza, 2006). Similarly, women tend to be viewed as either warm or competent, depending on whether they are stay-at-home mothers or professionals in the workforce (Cuddy, Fiske, & Glick, 2004). However, the stereotype content model also acknowledges that subgrouping among categories may occur and recent research has found that this can be true of a "top women leaders" category, in which women leaders who demonstrate their effectiveness are rated higher in communality, agency, and effectiveness than men (Rosette, & Tost, 2010).

Less work with the stereotype content model has looked at how stereotypes influence organizations and specifically how content might change longitudinally with co-worker experiences, task interdependence, and different

diversity ideologies (see Lee & Fiske, 2006; Plaut et al., 2009). Further development along these lines, as well as identification of additional means through which one can alter the content of the stereotypes one endorses, could prove beneficial to enhancing the experiences of employees in diverse settings.

Social Role Theory

One theory that attempts to explain the origin of sex stereotypes was proposed by Eagly (1987). She suggested that gender differences arise because men and women are differentially distributed into societal positions. That is, men are overrepresented in leadership and power positions (i.e., managers, leaders, business owners), whereas women are overrepresented in caring and nurturing roles (i.e., nurses, secretaries, teachers). Because of these differences, Eagly argues, people come to associate different sets of personality traits and abilities with men (i.e., they are more autonomous, better at making decisions) and women (i.e., they are more empathic and better caretakers). The differentiation between these attributes is often described in terms of a division between communal (i.e., sensitive, nurturing, feminine) and agentic (assertive, dominant, independent, masculine) characteristics (Eagly, 1987; Eagly & Karau, 2002; Madera et al., 2009). These associations can become self-fulfilling prophecies whereby men and women do become differentiated in their abilities and preferences (see also Wood, Christensen, Hebl, & Rothgerber, 1997), and this is further compounded by the fact that the roles that they are filling require different sets of behaviors (i.e., nurses do care for others, CEOs do have to make important and powerful decisions). Thus, Eagly (1987) argues that it is the distribution of men and women into societal positions that creates the differences. Furthermore, the role incongruity of women in leadership positions leads to prejudice and decreased abilities for women to perform and succeed in leadership positions as easily and as well as do men (see Eagly & Karau, 2002).

Recent research casts some positive light on the limitations that role incongruities prescribe. Specifically, Rosette and Tost (2010) found that when top leaders are shown to have attained success that can *only* be attributed to them (and not other factors), female (vs. male) top leaders were rated significantly higher on all dimensions of communal, agentic, and effective characteristics. Thus, once women have incontestably achieved success at the top echelons of society, they are finally accorded more favorable perceptions than are men, but the problem remains how to get them there and help them succeed.

Social role theory can be adapted further to understand many different types of majority/minority inequities. That is, there are other very obvious differential distributions of stigmatized and nonstigmatized individuals into society as well as organizations. We urge diversity researchers to consider the proxies that masculinity and femininity might be playing as differences in status (see also Ridgeway, 2009), and that the same sort of differential distributions into societal roles capture differences in other diversity characteristics, such as race and ethnicity, age, religious beliefs, pregnancy and parenthood status, and size. Future research that considers organization inequality as a function of higher- (vs. lower-) status groups more generally (not just men) as having increased access to resources, status, and power may yield more general findings and build more generalizable theories about what can be done to summon greater levels of equality for all organizational members.

Lack-of-Fit Model

Another very similar theory (and one certainly congruent with social role theory) that has been applied to try to explain gender inequities in the workplace is Heilman's Lack-of-Fit Model (Heilman, 1983, 1997). This theory is also based on an understanding that sex stereotypes obstruct the advancement of women in the corporate hierarchy, particularly at the highest levels. At such levels, Heilman argues, sex-typing of positions occurs and top management and executive-level corporate jobs are deemed to be masculine. Similarly, jobs that are high-powered, high paying, and important are more often categorized as men's rather than women's work (Duehr & Bono, 2006). The fact that most working women tend to be segregated in other fields (and the fact that women often experience mobility issues and discrimination within male-typed work) reinforces the image of their being "unfit" for jobs that are considered masculine.

While most of the research on the lack-of-fit model has focused on gender imbalances within organizations and particularly among gender and leadership, it is very applicable to the challenges that many other types of diverse and stigmatized individuals face in organizations. Recently, for instance, Sy et al. (2010) found that, consistent with the lack-of-fit model, ratings of leadership abilities and technical competence of Asian Americans increased when they were being rated for occupations that were race stereotypical (e.g., engineer) versus nonstereotypical (e.g., sales). Similarly, recent research has also

shown that "being White" (versus being non-White) was perceived to be more consistent with the business leader prototype (Rosette, Leonardelli, & Phillips, 2008).

Heilman (1983) prescribed that when a workplace role is inconsistent with the stereotypes of employees, they suffer from a perceived lack of fit to the role. This lack of fit results in decreased expectations of success by others, increased expectations of failure, and often ultimately decreases in the performance itself. We propose that the lack-of-fit theory, coupled with social role theory, could be the basis of even more diversity-related research. We believe urgent questions need to be addressed, such as how minority individuals can increase perceptions of their fitness. The answers are not simple, as Rudman (1998), for instance, shows that self-promotional behavior comes at a detriment to women but not to men. Furthermore, women are held to stricter standards for promotion, meaning that female upper-level managers need to receive higher performance ratings to be promoted than do men (Lyness & Heilman, 2006).

Summary

We summarized just some of the widely used and promising theories that explain and promote diversity within organizations. Additional theories exist and no doubt also have great potential. For instance, though initially developed to describe organizational patterns concerning deep-level diversity, Schneider's (1987) attraction–selection–attrition (ASA) could prove relevant to demographic diversity as well. In short, his model purports that people are attracted to organizations perceived to possess values similar to their own. Likewise, companies look to select employees they perceive as sharing their core values. When misfits occur, one (or both parties) recognize the lack of fit and act to correct it through the misfit voluntarily or involuntarily leaving the organization. The end result of this process is an organization wherein individuals tend to possess similar values and personality types. Perhaps this process also explains why many traditionally homogeneous organizations report such difficulty attracting and retaining employees belonging to underrepresented demographic groups. Although some research has tested thirds of the model independently, we know of no research examining the process more holistically. Thus, we encourage authors to utilize the theories described here; we also hope they will continue consulting and developing other theories as well.

HOT TOPICS AND UNRESOLVED ISSUES IN DIVERSITY RESEARCH

In this section, we consider some of the particularly important diversity-related questions driving research in the field, including our own. These represent hot topics, under-researched areas, and unresolved issues that are important for future research to address. There are four specific questions that we will address: (a) How do we get everyone interested in increasing diversity initiatives?; (b) How do we reduce discrimination so that we might directly or indirectly increase diversity?; (c) Is composition or climate a more important focal point for effective diversity management?; and (d) Why is moderator and mediator research particularly important for diversity research? We consider and discuss each of these in detail.

How Do We Get Everyone Interested in Increasing Diversity Initiatives/Issues?

A number of studies (many of which are very recent) reveal that the key to increasing diversity initiatives may be to carefully consider and recruit as stakeholders the different constituents in organizations. We begin by discussing minorities themselves and, subsequently, move on to a consideration of majority members.

It might be assumed that minorities (as defined by representation or power) would automatically and always favor diversity initiatives, particularly since such initiatives often focus on providing them with benefits (Avery, in press). However, research shows that this is not always the case. Many of these individuals sometimes experience costs, not just benefits, associated with diversity initiatives. One area in which this has been researched extensively is concerning affirmative action programs, or programs that give any special consideration to diverse members. The costs associated with being beneficiaries of these initiatives derive from both minorities' own psyches as well as from the reactions that they (sometimes accurately) perceive among others. Specifically, recipients who feel that they received handouts simply because of their race may experience self-doubts as well as feel compelled to be defensive against others (for a review, see Pratkanis & Turner, 1996). Moreover, people often assume that such beneficiaries have substandard levels of competency (see Heilman, 1997; Heilman, Block, & Lucas, 1992), and evidence suggests that sometimes such recipients are simply devalued if they are believed to be chosen simply because they are different (Jacobson & Koch, 1997). Indeed, much of the research on this topic suggests that the erroneous

convictions and negative affirmative action stereotypes are more powerful (and negatively so) than the actual helpfulness of affirmative action (see Barnes Nacoste, 1994).

Though many people assume that affirmative action programs entail strong preferential treatment (see Heilman & Blader, 2001), the reality is that few programs (except those mandated by the EEOC to address cases of organizational discrimination) actually work that way. So-called reverse discrimination is illegal, and affirmative action programs usually work by increasing the diversity within the initial pool of candidates. Thus, educating people about the details of affirmative action programs may do a great deal to curtail negative attitudes about them, both from beneficiaries and nonbeneficiaries (Doverspike, Taylor, & Arthur, 2000).

The other critical constituent to consider when planning or implementing diversity initiatives is the majority group. In fact, recent research on race shows that Whites may be particularly lukewarm about embracing multiculturalism because they, themselves, do not feel included (Plaut, Garnett, Buffardi, & Sanchez-Burks, in press) and do not believe that they will benefit (Doverspike et al., 2000). For instance, rather than suggest that Whites are prejudiced, Plaut et al. suggest that Whites (like everyone) have a basic need to belong (see Baumeister & Leary, 1995) and tend to view multiculturalism as an exclusionary ideology. Accordingly, they see it as a far less palatable option than do their minority counterparts. Increasing buy-in, then, necessitates the involvement of majority members and potentially framing diversity so that it is inclusive of and benefits everyone, as opposed to merely minorities. Plaut et al. further state that, given the power distribution in American organizations (e.g., 87% of CEOs and top management in private industries is White), it is simply critical to create messages that appeal to both minorities and majorities alike.

Additional research reveals that framing can dramatically and successfully influence perceptions about diversity. For instance, diversity initiatives tend to be viewed more favorably when they involve *instrumental justifications* (a framework suggesting that everyone stands to be a beneficiary) as opposed to *compensation justifications* (frameworks focusing on the benefits that protected groups receive and deserve to redress past discrimination; Knight, Hebl, Foster, & Mannix, 2003; Kravitz et al., 1997). Similarly, frameworks that are broad are rated more favorably than those with a narrow focus (Holladay, Knight, Paige, & Quinones, 2003), though some authors have cautioned that this broadening of diversity might distract the focus

of initiatives from dealing with inequality (Linnehan & Konrad, 1999).

Many people simply believe that frameworks and organizational diversity policies altogether should simply be colorblind, which is an ideology focused on the notion of sameness and that categories should be avoided or ignored. The problem with this idea of assimilation, however, is that research shows that despite individuals' best interests, people automatically and very quickly identify and characterize individuals according race, gender, and other categories (Cosmides, Tooby, & Kurzban, 2003). Furthermore, studies suggest that attempting to ignore or suppress information about diversity may actually lead individuals to act in more, not less, discriminatory ways (Macrae, Bodenhausen, Milnes, & Jetten, 1994; Madera, Hebl, & Beal, 2011; Plaut, Thomas, & Goren, 2009). Though we don't yet have a conclusive answer to the question of how to get everyone "on board" with diversity initiatives, the encouraging news is that research aimed at shedding light on this issue continues to proliferate.

How Do We Reduce Discrimination So That We Might Directly and Indirectly Increase Diversity?

The first step to reducing discrimination, we argue, is to accurately identify its various forms. Few would argue that the display of discriminatory behaviors in the United States has changed over time. In the past, discrimination tended to involve more *formal*, or very overt types of behaviors that explicitly (and often illegally) exclude individuals on the basis of their group membership from workplace and organizational opportunities. While there still exist examples of such flagrant types of discrimination, such overt displays are less common and tend to have legal repercussions or be subject to EEOC reparations. However, subtler forms of discrimination, which we refer to as *interpersonal* and others refer to as *incivilities* and *microinequities* (Cortina, 2008; Deitch et al., 2003; Rowe, 2008; see also Sanchez-Burks, Bartel, & Blount, 2009) are rampant in many organizations and have very negative consequences for individuals who are victimized. Such consequences may be particularly pernicious because such discrimination and the amount of it is often underestimated and undetected by majority members (see Swim & Miller, 1999).

Interpersonal discrimination often consists of nonverbal (e.g., avoiding eye contact, grimacing) as well as verbal (e.g., dismissive language) and paraverbal behaviors (e.g., tone of voice) that are not illegal to display. To differentiate the two forms of discrimination, Hebl, Foster,

Mannix, and Dovidio (2002) had research confederates apply for jobs at Texas retail stores wearing a hat that read (unbeknownst to them) either "Texan and proud" (non-stigmatized condition) or "gay and proud" (stigmatized condition). After the interaction, (a) confederates, (b) a visual observer, and (c) two independent raters (who later listened to audio recordings of interactions but were blind to the study's purpose) rated formal behaviors (e.g., being told a job was available, which researchers knew there was a priori; being allowed to complete an application) and interpersonal behaviors (e.g., eye contact, length of the interaction, smiling, frowning). Hebl et al. (2002) found that those wearing the "gay and proud" (vs. control) hats experienced significantly more interpersonal but not formal discrimination.

This pattern was replicated in subsequent studies with differing stigmas and contexts. For instance, visibly pregnant (versus nonpregnant) applicants received more hostile interpersonal behaviors when applying for jobs (Hebl et al., 2007), women wearing obesity prostheses (vs. those who did not) received more interpersonal discrimination when seeking customer service from retail personnel (King, Shapiro, Hebl, Singletary, & Turner, 2006), and male obese (versus non-obese) applicants and customers received more interpersonal but not formal discrimination (Hebl, Ruggs, & Williams, 2010). In addition, women (vs. men) in organizations (King et al., 2010), Arab (vs. non-Arab) job candidates (Derous, Nguyen, & Ryan, 2009) and Muslim (vs. non-Muslim) job applicants (King & Ahmad, in press) were also targeted with increased interpersonal but not necessarily formal discrimination. While discrimination in organizations has become more subtle, it has not necessarily become less pernicious and research shows both individual and organizational costs of interpersonal discrimination including decreased performance, reduced health outcomes, decreased purchasing behaviors, loss of profit, loss of valuable employees, and decreased equity (King & Cortina, 2010; Lim, Cortina, & Magley, 2008; King, Hebl, George, & Matusik, 2010; King et al., 2006; Singletary & Hebl, 2012; Word, Zanna, & Cooper, 1974).

The second step to reducing discrimination is to consider strategies that may be successful and how different constituents can enact them (we point readers who are interested in a detailed chapter of such strategies to Ruggs, Martinez, & Hebl, in press). To begin, those who are diverse, themselves, might wish to enact strategies to decrease discrimination (and ultimately increase diversity within organizations). Recent research has shown that strategies involving acknowledgment and/or disclosing (bringing attention directly to one's stigma rather than

ignoring it), increasing one's positivity and agreeableness (despite potentially negative expectations), and deindividuating oneself from stereotypical associations with a stigmatized status can all be at least somewhat effective strategies for individual targets of discrimination to pursue (Flynn, Chatman, & Spataro, 2001; Griffith & Hebl, 2002; Ragins, 2008; Ragins et al., 2007; Singletary & Hebl, 2009). Clearly, there is much more work to do to disentangle why, when, and how these strategies work, as well as their limitations.

Allies within organizations also can have a significant impact in reducing discrimination and increasing diversity (again, see Ruggs et al., in press). Allies might wish to enact such strategies because they (a) have friends who are experiencing discrimination, (b) feel empathic toward those who are victimized, or (c) feel otherwise compelled by a moral code or social imperative (see Martinez, 2012; Monteith, Ashburn-Nardo, Voils, & Czopp, 2002). Although there is less empirical research showing what is (and how it is) effective, allies can help set social norms within organizations that contribute to more inclusive work environments. One way that they can do this is to model positive attitudes toward minority-group employees, which has been shown to lead others to similarly adopt positive attitudes (Blanchard, Crandall, & Brigham, 1994; Thomas, 1999; Zitek & Hebl, 2007). Allies also can use their power to improve stigmatized employees' circumstances, access to resources, and support networks. Clearly, research shows that coworker support for stigmatized individuals particularly leads to positive organizational outcomes (e.g., Griffith & Hebl, 2002). Similarly, allies can join and support affinity groups and confront discrimination against stigmatized individuals within organizations. Though further studies are needed to address the limiting conditions and contexts, research shows that confronting can be a very successful tool for reducing discrimination and, ultimately, increasing and supporting diversity (Ashburn-Nardo, Morris, & Goodwin, 2008; Czopp, Monteith, & Mark, 2006).

Finally, larger entities can also act to reduce discrimination within organizations (see also Ruggs et al., in press). Recently, in fact, King and Cortina (2010) nicely argued that organizations have both financial and social imperatives to act in ways that protect individuals from experiencing discrimination. Specifically, they stated that organizations have corporate social responsibility (CSR), or an obligation to act for the social good of the communities that they serve. As such, there are many ways that organizations can reduce discrimination and enhance diversity. They may, for instance, select diversity-minded

recruitment, selection, and placement procedures that deter employees who do not hold equitable values. Recent studies have shown success in using procedures that include portraying on advertisement brochures diversity within the organization (Avery, Hernandez, & Hebl, 2004; Purdie-Vaughns, Steele, Davies, Dittmann, & Crosby, 2008), use of structured interviews and behavioral scripts to reduce negative stereotypes (Avery, Richeson, Hebl, & Ambady, 2009; Sacco et al., 2003), and specific top management instructions that focus employers on the use of legitimate performance criteria (Umphress et al., 2008).

We urge researchers to conduct more investigations aimed at generally uncovering and empirically demonstrating successful ways to reduce discrimination, both at the individual and group level. We further encourage researchers to show the cause-and-effect links between discrimination and reduced diversity, and to identify moderators and mediators of successful strategies. Finally, we believe that though it is difficult to do, more organizational research on diversity and discrimination-related constructs must be done within actual organizational settings.

The Composition Versus Climate Debate

Which Comes First?

Given the potential for diversity to be beneficial or detrimental to group and organizational functioning, it behooves scholars and organizations to determine the optimal strategies for managing it. A key debate within the literature on diversity management is whether the organization should focus on its composition or its climate in a reprise of the classic "Which came first—the chicken or the egg?" argument. By composition, we refer to the demographic makeup of a company's personnel. This may pertain to simple measures like the proportion of men, women, gays, or minorities within a unit, or could involve more complex indicators such as the standard deviation of employee ages. By climate, we refer to shared perceptions regarding the organizational valuation of diversity and inclusion. This may involve surveys designed to assess these perceptions or more objective indicators such as the extent to which an organization is integrated across hierarchical levels (Cox, 1994).

Proponents of composition argue that a company should concern itself primarily with attracting and selecting a diverse workforce. The presumption is that a diverse workforce, in and of itself, will force the organization to diversify its approach to management, thereby making the organization more inclusive (Kossek, Markel, & McHugh, 2003). In a sense, this approach extrapolates the contact

hypothesis (Allport, 1954) from the individual to the organizational level of analysis. Generally speaking, the contact hypothesis proposed that individuals become more tolerant of and sensitive to the needs of dissimilar others as their level of exposure to these individuals increases. Research on it tends to support this premise, especially when the contact takes place between equal-status individuals in an affirming environment (Pettigrew & Tropp, 2006).

At the organizational level, however, the notion that composition precedes or even relates to climate has met with considerably less support. For instance, McKay, Avery, and Morris (2008) reported very small correlations between the percentages of female ($r = -0.03$, *ns*) and minority ($r = 0.12$, $p < 0.05$) associates and a retail store's diversity climate. Likewise, Gonzalez and DeNisi (2009) observed small, nonsignificant correlations between demographic diversity and diversity climate in restaurants. Looking at 142 banks, Pugh, Dietz, Brief, and Wiley (2008) found the climate–correlation relationship to be conditional, depending on the composition of the surrounding community. Finally, in one of the most direct tests of the composition-begets-climate hypothesis, Kossek et al. (2003) examined changes in composition and climate over an 8-year period at a university. Their results indicated that increasing the level of diversity in a department had no consistent effect on the departmental diversity climate. This led them to conclude that “HR strategies that focus on structural change without working to develop supportive group norms and positive climate may be inadequate change strategies” (p. 328).

While the literature has produced little evidence that composition affects climate, there have been a number of findings to support the plausibility of the reversed causal linkage. From a staffing standpoint, authors have demonstrated that a hospitable diversity climate can aid in attracting (Avery & McKay, 2006; Martins & Parsons, 2007; McKay & Avery, 2006) and selecting (Petersen & Dietz, 2008; Umphress, Simmons, Boswell, & Triana, 2008; Ziegert & Hanges, 2005) a broader spectrum of applicants. Several studies also indicate that diversity climates or perceptions thereof influence the attitudes and behaviors of incumbent employees in a manner likely to influence the organization's composition. For example, King, Hebl, Matusik, and George (2010) found that tokenism influences women's perceptions of diversity climate, which in turn influence their job satisfaction, affective commitment, job stress, intent to remain, and organizational citizenship. Thus, organizations with less hospitable diversity climates may find it difficult to retain their female employees.

Other authors (Avery et al., 2007; Gonzalez & DeNisi, 2009; McKay et al., 2007) linked diversity climate perceptions to employee withdrawal (absenteeism and turnover intentions) and showed these linkages to be especially pronounced among Black employees. Moreover, diversity climates also influence demographic differences in actual job performance, with these differences being significantly smaller when climates are more supportive of diversity (McKay et al., 2008). Collectively, these studies imply that diversity climate may be vital to attracting, promoting, and retaining traditionally underrepresented employees.

Which Is More Impactful?

Besides the uncertainty about whether one precedes the other, there is also the question of the relative influence of composition and climate on organizational phenomena of interest. As mentioned previously, the literature linking diversity to organizational and team performance is quite inconsistent, which has given rise to a recent wave of research looking at moderators (the next section contains a detailed discussion of this research). Of the recent literature to focus on main effects, one reported a negative relationship between racial diversity and profitability along with null effects of age and sex diversity (Sacco & Schmitt, 2005), whereas the other tied race and gender diversity to positive outcomes such as more customers, sales revenue, and profitability (Herring, 2009). Literature investigating the main effects of climate on organizational and unit-level outcomes has proven far more consistent. For instance, more hospitable diversity climates coincide with greater sales growth (McKay, Avery, & Morris, 2009) and customer satisfaction (McKay, Avery, Liao, & Morris, *in press*).

A few studies have included both climate and composition at the unit levels of analysis. In these studies, the correlations between climate, composition, and the focal outcomes paint a bit of a mixed picture. For instance, in their examination of restaurants ($N = 26$), Gonzalez and DeNisi (2009) examined diversity climate, gender diversity, racial diversity, return on profit, return on income, and productivity. The correlations for diversity climate ($r_s = -0.13, 0.02$, and -0.04), gender heterogeneity ($r_s = 0.02, 0.08$, and 0.08), and racial heterogeneity ($r_s = 0.00, 0.09$, and -0.13) were all quite small and several were negative. In McKay et al.'s (2009) examination of 654 retail stores, diversity climate ($r = 0.20$) and the percentage of minority associates ($r = 0.13$) correlated positively with sales growth, but the percentage of female associates correlated negatively ($r = -0.08$). Likewise, McKay et al. (*in press*) reported similar patterns between climate ($r = 0.20$)

and composition (percent minority $r = 0.12$ and percent female $r = 0.06$) with customer satisfaction in 769 retail stores. It should be noted, however, that because White and female employees represented the majority in those stores, this suggests a similar (opposite) pattern of association for racioethnic (gender) diversity. Though it is not possible to make any conclusive statements about the relative importance of climate and composition from these findings, perhaps the most notable results from these studies are the interactions they reported between the two. It appears that diversity climates are most impactful when there is more racioethnic or moderate gender diversity within the unit (Gonzalez & DeNisi, 2009; McKay et al., in press).

Logic suggests organizations focus on their climates prior to investing resources in diversifying their composition for two key reasons. First, an organization's diversity climate is often more controllable than its composition, which may be influenced by a number of relatively uncontrollable factors such as community factors (McKay & Avery, 2006). Second, efforts to attract employees belonging to groups currently underrepresented in the organization are likely to prove ineffective or even wasteful if the company hasn't taken steps to ensure that these individuals will be supported adequately should they opt to work there. Accordingly, we encourage researchers to devote more attention to diversity climate, which has been vastly understudied in relation to composition. In particular, there is a need for greater understanding of its antecedents, especially in light of its seemingly many important consequences.

The Devil Is in the Details—Moderators and Mediators of Diversity Effects

A good deal of the early research on diversity focused primarily on determining its simple effects on unit-level outcomes such as performance (Williams & O'Reilly, 1998). Over time, however, the literature has revealed that the relationship between diversity and performance is anything but simple (van Knippenberg & Schippers, 2007). The consistent inconsistency of diversity's effects lead many researchers to refocus their attention on identifying boundary conditions (i.e., moderators). Moreover, scholars (e.g., Lawrence, 1997) also began to call for greater attention to explicating the mechanisms underlying relationships between diversity and outcomes of interest (i.e., mediators). Subsequently, it became commonplace for research to explore when and why diversity sometimes influences performance.

Moderators

The recent literature is replete with scholarly attempts to identify moderators. One promising variable appears to be the type of leadership taking place within the group. For instance, groups experiencing more transformational and inclusive leadership tend to experience more favorable outcomes of diversity (Kearney & Gebert, 2009; Nishii & Mayer, 2009). Individual differences also appear important, as members' diversity beliefs (Homan et al., 2007) and need for cognition (Kearney et al., 2009) moderate the effect of diversity on performance. Finally, there are several contextual moderators as well. From a structural standpoint, the diversity configuration of the group (i.e., faultlines vs. cross-cutting), task complexity, and group size moderate effects of age and gender diversity on performance and health (Sawyer, Houlette, & Yeagley, 2006; Wegge, Roth, Neubach, Schmidt, & Kanfer, 2008) with diversity appearing more beneficial for smaller groups with cross-cutting characteristics working on more complex tasks. One seemingly intuitive moderator that has yet to receive any support, however, is the composition of a unit's customers. In fact, the two recent studies to examine this possibility found no consistent patterns for racial or gender employee-customer matching (Leonard, Levine, & Joshi, 2004; Sacco & Schmitt, 2005).

In a recent meta-analysis of the role of context in the team diversity–performance relationship, Joshi and Roh (2009) helped to identify a number of additional situational boundary conditions. Though the simple effects they observed for diversity were very small (r s ranged between -0.06 and 0.13), significantly larger effects were detected in certain circumstances. First, they found that the demographic composition of the occupation influenced the diversity–performance relationship, with the effects of gender and race diversity being more positive in more evenly balanced (as opposed to primarily male or White) settings. Second, the industrial setting was also important, with relations-oriented (which included demographics) diversity being positively related to performance in service organizations ($r = 0.07$), but negatively related to performance in manufacturing ($r = -0.04$) and technology ($r = -0.18$) companies. Third, relations-oriented diversity positively predicted performance of independent teams ($r = 0.08$), negatively predicted performance of moderately interdependent teams ($r = -0.12$), and failed to significantly predict performance of highly interdependent teams. Finally, the duration of the team proved influential, as relations-oriented diversity was helpful in shorter-term ($r = 0.09$) but hurtful in longer-term teams ($r = -0.14$).

Collectively, the preceding literature demonstrates the importance of continuing to identify boundary conditions of the effects of diversity. Although it is convenient to think in terms of simple main effects, it considerably underestimates the complexity of diversity's impact on groups and organizations. Consequently, we urge future researchers to avoid the temptation of addressing the question of whether diversity helps or hinders performance. Instead, a more fruitful pursuit is to focus on stipulating the conditions under which diversity is more prone to enhance or diminish the bottom line.

Mediators

In addition to investigating when diversity influences outcomes, it is also of interest to determine why such a relationship occurs. Many researchers within the diversity literature have focused on doing just that. For instance, one underlying mechanism, information elaboration (van Knippenberg et al., 2004), was discussed at some length previously in this chapter. The basic gist of that discussion was that diversity sometimes leads to an exchange of information that may help the group to make more creative, well-informed decisions (Dahlin et al., 2005). This enhanced decision making, in turn, should help the group perform at a higher level than if the information elaboration had not taken place (Homan et al., 2007; Kearney & Gebert, 2009;). Thus, information exchange mediates the relationship between diversity and performance.

In a similar vein, researchers have proposed learning as a potential mediating mechanism. If dissimilar individuals commonly possess different sources of information, perspectives, and worldviews, putting these individuals together could facilitate their learning from one another. To test this premise, Gibson and Vermeulen (2003) studied more than 150 teams working in medicine and pharmaceuticals. In particular, they were interested in the impact of demographic subgroups (i.e., the extent to which members of one demographic group tend to also belong to another particular group). Their findings revealed that moderate subgrouping yielded the most learning. Furthermore, the data suggested that both very homogeneous and heterogeneous teams engaged in more learning behavior after statistically accounting for the impact of subgroups. To the extent that more diverse group members learn more from each other than do homogeneous group members, it should follow that this learning may translate into differences in performance.

A somewhat different approach to understanding how diversity influences performance builds on social identity theory. According to Swann et al. (2004), verification (i.e.,

getting others in one's group to see you as you see yourself) is a potential mediator of the diversity–performance linkage. Building on the learning linkage described above, diversity often encourages group members to learn from one another. In the process of doing so, they are likely to learn about one another as well. As this revelatory process unfolds, verification should occur, thereby enhancing members' level of identification with the group. The more members identify with the group, the more likely they are to perceive its fate as their own and invest themselves in helping the group to achieve its goals. Hence, verification may mediate the relationship between diversity and performance.

It is important to recognize that the most insightful contributions to understanding diversity's effects are those integrating moderation and mediation into a single model (Edwards & Lambert, 2007). Empirical investigation of the simple relationships between diversity and the three mediators discussed in this section is likely to yield results comparable to those obtained when focusing on the diversity–performance linkage (i.e., inconsistent findings). In other words, the diversity–mediator and mediator–performance relationships are probably contingent on many of the moderators of the diversity–performance linkage. Accordingly, we encourage scholarly engagement in rigorous theoretical development and testing of models combining moderation and mediation. In doing so, we also urge authors to consider and explicitly specify the stage(s) at which the moderation should be expected to take place.

Summary

Although a number of critical issues remain unresolved within the diversity literature, we identified four key issues we believed to be particularly important. Understanding how to elicit and build support for diversity initiatives will only grow in importance as the level of heterogeneity within organizations continues to increase (Avery, in press). Having greater diversity also may increase the potential for misunderstanding, competition over resources, and, thus, discrimination. Accordingly, it is important for organizations to understand how best to allocate their resources to create an environment supportive of diversity. This means research will need to explore the many nuances defining the diversity terrain by explicating boundary conditions and mediating mechanisms of diversity's effects on organizational outcomes. In reviewing the status quo with respect to current answers to these pressing issues, we hope to have provided readers with a sense of where we believe diversity research is headed and the course it will need to follow if it is to achieve its aims.

CONCLUSION

The purpose of this chapter was to provide an update on the literature investigating the effects of diversity in organizations since the appearance of the last volume of this *Handbook* in 2003. In the course of organizing and reviewing this literature, a number of things became clear. First, the study of diversity is quite healthy. It is impressive to see how much scholarship on the topic has made its way into the top outlets in our field during the early 21st century. Moreover, there is excellent research on diversity that appeared in journals that we did not cover here. It was immensely difficult trying to include all of the recent literature in this chapter and, admittedly, some topics were under-covered in our review (e.g., adverse impact, affirmative action). This should not, however, be interpreted as an indication that we see these topics as unimportant. Rather, there are practical limitations to what can be included in any one review and it is unfortunate that many deserving articles had to be excluded from our review for space considerations.

Second, it is impressive to see the ongoing development, utilization, testing, and refinement of theory within the diversity literature. This is especially welcome in light of the fact that past diversity scholarship often received criticism for its lack of solid theoretical grounding (e.g., Nkomo, 1992). Though we limited our focus to seven theories, there are certainly others that could have been included (e.g., demographic faultlines, the interactional model of cultural diversity, tokenism, stereotype threat). As researchers continue to extend existing theory and develop new theory to account for diversity phenomena, we urge them to consider how these theories apply (or do not apply) across the various types of diversity. Some theories may prove more relevant to some types of diversity than to others. For instance, a psychological process like identity comprehension (Thatcher & Greer, 2008) may apply better to the study of social identities that are often highly valued (e.g., race/ethnicity, sex, religion) as opposed to those that are not (e.g., obese, drug addict). Thus, a useful aspect of theory development is the determination of the theory's boundary conditions.

Third, despite the enormous progress seen within the literature, there remains a great deal left to learn. We've discovered that the answer to the question of whether diversity helps or hurts performance is a resounding . . . it depends. Studies continue to unravel the contingencies and intervening mechanisms of the diversity–performance relationship and more work is needed along both fronts. We hope scholars continue diversifying their approaches

as they enhance our understanding of how diversity affects the bottom line.

Several decades have passed since the intersection of work and family roles has become recognized as an important area of study within industrial and organizational (I-O) psychology. Perhaps initially considered a “fringe” area of research outside of mainstream I-O (as evidence note that the first edition of this Handbook did not include a work–family chapter), work–family scholarship has flourished over the past several decades.

Concerted interest in work and family issues within I-O psychology can be traced to Zedeck’s 1987 Society for Industrial and Organizational Psychology (SIOP) presidential address, in which he called for I-O psychologists to study the relationship between work and family roles. The publication of the edited volume entitled, *Work, Family, and Organizations* soon followed (Zedeck, 1992). Today, sessions concerning work–family frequently appear on the program of the annual *Society for Industrial and Organizational Psychology* conference and a notable number of work–family articles are being published in top journals such as the *Journal of Applied Psychology* and *Personnel Psychology*. Beyond I-O psychology, the field of work–family research has ripened to the point that a separate membership society for work and family researchers, *The Work–Family Researchers Network*, comprised of individuals from multiple disciplines, is in the process of being formed with an initial conference planned for June 2012.

Indeed, it appears that work-and-family research has come of age.

Chapter Overview

As a maturing area of research there have been numerous broad reviews of the literature in recent years (e.g., Allen, 2012; Chang, McDonald, & Burton, 2010; Greenhaus & Allen, 2010; Hammer & Zimmerman, 2011; Kossek, Baltes, & Matthews, 2011). The intent of the current chapter is review research with regard to the intersection of work and family roles, but with a greater emphasis on new or expanding areas of inquiry. The chapter unfolds as follows. I begin by describing literature that has investigated positive and negative interdependences between work and family roles, followed by a review of the work–family balance literature. I then review individual differences associated with work–family. This is followed by a review of organizational and national supports for work–family. Next work–family issues are reviewed from a cross-national perspective. The chapter closes with proposed directions for future research.

Before turning to the review, a few comments regarding terms are needed. Astute readers may note the use of the term *work–family* as opposed to *work–life* or *work–nonwork*. These terms are often used interchangeably in the literature. In the current chapter, I rely on

the term *work–family* as an umbrella term intended to include all research involving the juxtaposition of multiple life roles. Some have criticized the “work–family” frame as too narrow in that it neglects other life roles important to individuals, thus constraining research and theory. Although such debates are important dialogue for the field, they are outside of the scope of this chapter. The interested reader is referred to Moen (2011) for an excellent discussion of the issues.

WORK AND FAMILY INTERDEPENDENCIES

Overview

While *work–family* has become part of the common lexicon, it is typically framed as a struggle. Simultaneous engagement in work and family roles is characterized as a phenomenon fraught with conflict. Indeed, work–family conflict is arguably the most common topic of study within the work–family literature. Research consistently demonstrates that the management of work and family roles can be a challenge. However, combining work and family roles also provides benefits and opportunities for enrichment. The following sections provide a brief review of literature focused on both the positive and the negative aspects of combining work and family roles.

Negative Work–Family Linkage

Conflict between work and family roles has been a major topic of study within the work–family literature. The scarcity hypothesis serves as a theoretical basis for work–family role conflict (Goode, 1960). The *scarcity hypothesis* suggests that individuals have a finite amount of time, energy, and attention. The more roles an individual occupies, the more likely it is that those limited resources will become depleted. Kahn, Wolfe, Quinn, Snoek, and Rosenthal’s (1964) work with regard to organizational stress has also been an influential theoretical underpinning for work–family conflict research. Kahn et al. coined the term *interrole conflict* to describe when pressures in one role become incompatible with the pressures from another role. Greenhaus and Beutell (1985) extended Kahn et al.’s (1964) definition of interrole conflict to develop the definition of work–family conflict most commonly used by work–family scholars. Specifically, work–family conflict is defined as “a form of interrole conflict in which the role pressures from the work and family domains are mutually incompatible in some

respect” (p. 77). Work–family conflict is the mechanism that links constructs within one domain such as job stressors with constructs in other domains such as family strain (Frone, Russell, & Cooper, 1992).

Although early research often conceptualized work–family conflict globally (e.g. “My work and family interfere with each other”) (e.g., Quinn & Staines, 1979), current research recognizes the directionality of the conflict. Family interference with work (FIW) is a distinct construct from work interference with family (WIF), with each direction demonstrating unique antecedents and consequences (e.g., Aryee, Fields, & Luk, 1999; Carlson, 1999). As noted by Greenhaus and Powell (2003), the directionality of a conflict between work and family only becomes apparent after the individual makes a decision regarding the resolution of competing simultaneous pressures emanating from work and family roles. The family role appears to be more permeable than the work role in that mean levels of WIF tend to be higher than those of FIW (Bellavia & Frone, 2005).

In addition to direction of the conflict, three different types of conflict are recognized in the literature: time-based conflict, strain-based conflict, and behavior-based conflict (Carlson, Kacmar, & Williams, 2000; Greenhaus & Beutell, 1985). Time-based conflict occurs when time spent on tasks associated with one role inhibits the completion of responsibilities in another role. Strain-based conflict arises when pressures from one role make it difficult to fulfill the requirements in another role. Finally, behavior-based conflict occurs when behaviors necessary for one role are incompatible with behavior patterns necessary in the other role.

Predictors

Several meta-analyses have cogently summarized the research regarding predictors of work–family conflict in recent years (Byron, 2005; Ford, Heinen, & Langkamer, 2007; Michel, Kotrba, Mitchelson, Clark, & Baltes, 2011). Because individual differences (exclusive of demographics) and organizational practices are reviewed in separate sections as growing areas of research emphasis, this section focuses on a summary of research relating demographic and situational variables to work–family conflict. Due to the large number of existing available reviews, the current review is brief.

Several demographic variables have been studied frequently as predictors of work–family conflict. Sex in particular has been extensively investigated (Korabik, McElwain, & Chappell, 2008; Powell & Greenhaus, 2010). Although common wisdom is that because women

tend to have greater family demands while men tend to have greater work demands, women experience greater FIW than do men and men experience greater WIF than do women, meta-analytic research finds very small effects associated with these relationships (Byron, 2005). Specifically, Byron reported meta-analytic effect sizes of -0.03 between sex and WIF and 0.06 between sex and FIW such that men tend to report slightly more WIF while women tend to report slightly more FIW.

The effects associated with parental status and work–family conflict are more robust than those regarding sex. Number of children at home consistently relates to reports of greater WIF and FIW (e.g., Bruck & Allen; Byron, 2005; Carlson, 1999). There is also some evidence that parental status and sex interact. Parenthood appears to increase both directions of interference to a greater degree for women than for men. Specifically, in her meta-analysis, Byron found that when samples were comprised of more parents the gender difference in the experience of WIF and FIW widened such that women reported significantly more WIF and FIW than did fathers.

Marital status is another variable that demonstrates little main effect but appears to be moderated by parental status (Byron, 2005). Married and single employees without children report similar levels of WIF and FIW, but single parents report more WIF and FIW than do married parents (Byron, 2005). Marital type (single- versus dual-earner) has also been meta-analytically examined. Members of a dual-earner couple are expected to experience more work–family conflict than are members of a single-earner couple (e.g., Higgins & Duxbury, 1992), but research shows few differences.

Situational variables commonly studied as predictors of work–family conflict include role stressors and role involvement. Role predictors are domain specific in that the predictors of WIF tend to reside primarily in the work domain (e.g., work demands) while the predictors of FIW tend to reside primarily in the family domain (e.g., family demands). Role stressors include variables such as role conflict, role ambiguity, role demands, and role overload. Work role stressors consistently relate to WIF while family role stressors consistently relate to FIW (Byron, 2005; Michel, Kotrba et al., 2011). Role involvement can be assessed both subjectively (e.g., job involvement) and objectively (e.g., hours spent working). The effect sizes associated with role involvement tend to be smaller than those of role stressors (Byron, 2005; Michel, Kotrba et al., 2011). In addition, the magnitude of the observed relationships tends to be stronger with regard

to work role involvement and WIF than with regard to family role involvement and FIW.

Outcomes

A wide variety of outcomes have been associated with work–family conflict. Multiple informative quantitative and qualitative reviews of this literature exist (Allen, Herst, Bruck, & Sutton, 2000; Amstad, Meier, Fasel, Elfering, & Semmer, 2011; Greenhaus, Allen, & Spector, 2006; Kossek & Ozeki, 1998). Research consistently shows that both directions of work–family conflict relate to job satisfaction, life satisfaction, marital satisfaction, burnout, and both physical and psychological strains.

Domain specificity is generally less supported with regard to outcomes of work–family conflict. Early models of the work–family interface posed outcomes specific to the receiving domain of the conflict (e.g., Frone, Russell, & Cooper, 1992; Frone et al., 1997). For example, in these models job satisfaction is linked directly to FIW while family satisfaction is linked directly to WIF. Two recent meta-analyses have investigated the domain specificity of outcomes. Amstad et al. reported that WIF was more strongly associated with work-related than family-related outcomes and that FIW was more strongly associated with family-related outcomes than work-related outcomes. Another study looking solely at job and family satisfaction within a meta-analytic path model framework came to a similar conclusion (Shockley & Singla, 2011). This pattern is thought to occur because blame for the conflict is attributed to the domain that was the originating source of the conflict (Grandey, Cordeiro, & Crouter, 2005; Lapierre, Spector, Allen, Poelmans et al., 2008; Shockley & Singla, 2011).

Given the robust relationships linking work–family conflict with health outcomes, one growing area of interest is the relationship between multiple role engagement and health behavior. One of the earliest health behaviors to be linked with work–family conflict was alcohol use. Frone and colleagues consistently have found that work–family conflict is associated with alcohol problems (e.g., Frone et al., 1997; Grzywacz & Bass, 2003). Wang, Liu, Zhan, and Shi (2010) recently extended this line of research. Based on a daily experience sampling study, they found that WIF, but not FIW, had a significant within-subject main effect on daily alcohol use. Recent research has investigated the link between work–family conflict and health behaviors associated with diet and exercise (e.g., Allen & Armstrong, 2006; Devine, Stoddard, Barbeau, Naishadham, & Sorensen, 2007; Roos, Sarlio-Lahteenkorva, Lallukka, & Lahelma, 2007). For

example, greater FIW has been associated with eating more high-fat foods and less physical activity (Allen & Armstrong, 2006). Allen and Armstrong also reported that WIF was associated with eating fewer healthy foods. Researchers attribute diet and exercise findings to perceptions of time scarcity. Food choices are used as a way to help cope with competing time demands between work and family (Devine, Jastran, Jabs, Wethington, Farell, & Bisogni, 2006). Only 13% of parents report activities such as eating right and exercising as a strategy used to *help* meet the demands and expectations of work and home (Pitt-Catsouphes, Matz-Costa, & MacDermid, 2007). Research has also linked WIF with obesity (Grzywacz, 2000) and with weight gain (Lallukka, Laaksonen, Martikainen, Sarlio-Lahteenkorva, & Lahelma, 2005). Finally, a growing body of research has linked work–family conflict with sleep quality (e.g., Lallukka, Rahkonen, Lahelma, & Arber, 2010; Nylen, Melin, & Laflamme, 2007).

Positive Work–Family Linkage

In contrast to the emphasis on conflicts between work and family roles, there is a growing body of research investigating the positive interdependencies that exist as a result of combining work and family roles. This view is consistent with current movements such as positive psychology (e.g., Seligman, Steen, Park, & Peterson, 2005) and positive organizational scholarship (e.g., Luthans, 2002). The theoretical basis for positive work–family relationships is based on expansion theory (Marks, 1977; Sieber, 1974). Expansion theory suggests that multiple roles result in greater access to resources. This perspective suggests that individuals' supply of energy is expandable and that multiple roles can increase psychological well-being (e.g., Barnett & Baruch, 1985; Thoits, 1983).

Multiple concepts have been developed to represent positive linkages between work and family roles. These include positive spillover (e.g., Crouter, 1984; Hanson, Hammer, & Colton, 2006), work–family facilitation (Grzywacz & Bass, 2003; Wayne, Musisca, & Fleeson, 2004), and work–family enrichment (Carlson Kacmar, Wayne, & Grzywacz, 2006; Greenhaus & Powell, 2006). The distinction between the various constructs is not consistently clear, but each reflects the perspective that combining multiple roles can result in beneficial outcomes for the individual. Similar to the bidirectionality of work–family conflict, it is recognized that work can benefit family as well as that family can benefit work.

Positive spillover is defined as the transfer of generative mood, skills, behaviors, and values from work to family or from family to work (Edwards & Rothbard, 2000; Hanson et al., 2006). Hanson et al. developed a measure of positive spillover that captures three types of work-to-family positive spillover: affective, behavior-based instrumental, and values-based. *Facilitation* refers to the extent that engagement in one life domain provides gains that contribute to enhanced functions in another life domain (Wayne, Grzywacz, Carlson, & Kacmar, 2007). It has also been suggested that the term *facilitation* be used to signify theory and research that pertains to system-level issues within the work–family interface (Grzywacz, Carlson, Kacmar, & Wayne, 2007). Finally, *enrichment* is defined as the extent that experiences in one role improve the quality of life (performance and positive affect) in the other role through the transfer of resources from one role to the other (Greenhaus & Powell, 2006). Greenhaus and Powell identify five types of resources that can be role generated, including skills and perspectives, psychological and physical resources, social-capital resources, flexibility, and material resources.

Carlson et al. (2006) developed a measure of enrichment. Work-to-family enrichment was composed of three dimensions: developmental, affect, and capital. Family-to-work enrichment was comprised of three dimensions, development, affect, and efficiency.

As noted previously, the distinction between these constructs is not completely clear. Wayne (2009) developed a conceptual framework intended to explain the differences among the three. She suggested that *positive spillover* occurs when an individual transfers the gains from one domain to a second domain. For example, the skills learned at work are transferred and applied at home. In order for *enrichment* to occur, the individual must successfully apply the gains to the other domain. That is, for enrichment to occur, the individual would not only have to transfer the skills learned from one domain to another (positive spillover), but would also have to experience improved performance or quality of life as a result. Facilitation occurs when the skills learned from the workplace result in improvement in function at the level of the family unit. This framework suggests a type of temporal ordering such that enrichment follows from spillover and that facilitation follows from enrichment.

Recent research has attempted to investigate the distinction between the constructs based on a simultaneous comparison of Carlson et al.'s (2006) work–family enrichment measure to Hanson et al.'s (2006) work–family positive spillover measure. Consistent with the framework

developed by Wayne (2009), Masuda, Nicklin, McNall, and Allen (2012) found that work–family enrichment mediated the relationship between work–family positive spillover and job satisfaction while work–family positive spillover did not mediate the relationship between work–family enrichment and job satisfaction. The authors also found that multiple items cross-loaded across the two measures, suggesting further development of these measures is needed.

In the following sections, predictors and outcomes of positive synergies between work and family are reviewed. For the purpose of simplicity, the term *enhancement* is used as a generic way to denote research on the positive benefits of multiple role engagement. WFE is used to denote enhancement that flows from work to family and FWE is used to denote enhancement that flows from family to work.

Predictors

A growing, but still limited set of predictors has been associated with work–family enhancement to date. The most consistent finding has been an association between gender and enhancement such that women tend to report higher levels of enhancement than do men (e.g., Aryee, Srinivas, & Tan, 2005; Powell & Greenhaus, 2010; van Steenbergen, Ellemers, & Mooijaart, 2007).

In their model of the work–family enrichment process, Greenhaus and Powell (2006) suggested that the predictors of enrichment would be resources that are acquired from the originating domain. Similar to the domain specificity findings with regard to predictors of work–family conflict, such specificity has generally been supported in the enhancement literature. Specifically, family variables such as psychological involvement in the family and marital role commitment have been found to predict FWE (e.g., Allis & O’Driscoll, 2008; Graves, Ohlott, & Ruderman, 2007) while work-related variables such as job involvement and characteristics of the job have been associated with WFE (Aryee et al., 2005; Grzywacz & Butler, 2005).

Outcomes

The outcomes associated with enhancement tend to be similar to those associated with work–family conflict, but with opposite effects. The research regarding enhancement and outcomes was recently summarized in a meta-analytic study (McNall, Nicklin, & Masuda, 2010). McNall et al. reported that both WFE and FWE were positively associated with job satisfaction, organizational commitment, family satisfaction, physical health, and mental health.

In addition, life satisfaction was associated with WFE. Turnover intent was not associated with either direction of enhancement. The authors also reported moderator effects. Specifically, the relationship between WFE and job satisfaction, as well as between FWE and job satisfaction, was stronger in samples that consisted of a majority of women. Sex similarly moderated the WFE–family satisfaction relationship.

With regard to domain specificity effects, existing research shows that WFE tends to be more strongly linked to work outcomes than is FWE while FWE relates more strongly to family related outcomes than does WFE (e.g., McNall et al., 2010; Shockley & Singla, 2011; Wayne et al., 2004). Thus, similar to the findings with regard to work–family conflict, reactions to enhancement are primarily associated with the role from which the enhancement originates.

Summary

Over the past several decades the study of work–family conflict has been a dominant force within the work–family literature. Recently, a great deal of attention has also been given to the positive aspects of multiple role engagement. In concert, findings suggest that role stressors are the strongest predictors of work–family conflict. The strongest predictors of role enhancement have yet to emerge. As will be discussed below, dispositional variables are likely a common predictor to both. Generally speaking, positive outcomes accrue to those that experience work–family enhancement while negative outcomes accrue to those who report work–family conflict.

WORK–FAMILY BALANCE

Work–family balance is emerging as a distinct topic of study within the work–family literature. Although the term has been equated with low conflict between work and family roles (e.g., Hill, Hawkins, Ferris, & Weitzman, 2001) or as the combination of low conflict and high work–family facilitation (e.g., Frone, 2003), researchers have begun to recognize work–family balance as a unique construct (Grzywacz & Carlson, 2007; Greenhaus & Allen, 2010). In contrast to constructs such as work–family conflict and work–family enrichment, work–family balance is not a linking mechanism between work and family because it does not specify how conditions or experiences in one role are causally related to conditions or experiences in the other role (Greenhaus,

Collins, & Shaw, 2003). Rather, it reflects an overall interrole assessment of compatibility between work and family roles. Several studies provide psychometric evidence to support the distinction between the three constructs (Allen, Greenhaus, & Edwards, 2010; Carlson, Grzywacz, & Zivnuska, 2009). However, among those who recognize balance as distinct from work–family conflict and work–family enrichment, conceptual definitions differ.

Grzywacz and Carlson (2007) contend that balance should be viewed as a social construct. More specifically, they define balance as “accomplishment of role-related expectations that are negotiated and shared between an individual and his or her role-related partners in the work and family domains.” Greenhaus and Allen (2010) define work–family balance as “the extent to which an individual’s effectiveness and satisfaction in work and family roles are compatible with the individual’s life role priorities at a given point in time.” Life role priority refers to the relative priority, focus, or emphasis placed on different life roles (Friedman & Greenhaus, 2000).

Within research that recognizes balance as a construct unique from work–family conflict and work–family enrichment, it has been operationalized in a variety of ways that include single items of perceived success at balancing work and family, satisfaction with balance, role accomplishment as perceived by others, and agreement that work and family roles are balanced (e.g., Allen et al., 2010; Carlson et al., 2009; Valcour, 2007).

Predictors and Outcomes

Given that a focus on balance as a unique construct independent from work–family conflict and work–family enrichment is relatively new, a limited amount of research exists regarding predictors and outcomes. Greenhaus and Allen (2010) theorize that both work–family conflict and work–family enrichment serve as predictors of work–family balance. Although the causal ordering of variables is not clear, several studies have demonstrated that balance can be factor-analytically distinguished from work–family conflict (Allen et al., 2010; Carlson et al., 2009) as well as from work–family enrichment (Carlson et al., 2009). Time spent in various activities is one predictor with longer work hours associated with less perceived balance and more time spent engaged in quality time with children positively associated with perceived balance (Milkie, Kendig, Nomaguchi, & Denny, 2010; Valcour, 2007). Recent research has also associated trait mindfulness with work–family balance (Allen & Kiburz, 2012). Outcomes associated with work–family balance

include job satisfaction, organizational commitment, family satisfaction, family functioning, and life satisfaction (Allen et al., 2010; Carlson et al., 2009).

INDIVIDUAL DIFFERENCES AND WORK–FAMILY

The role of individual differences in the work–family interface has become of increasing interest within the work–family literature. Developed areas of research as well as emerging topics of inquiry are discussed.

Dispositional Variables

Dispositional variables have been associated with both work–family conflict and work–family enhancement (e.g., Bruck & Allen, 2003; Grzywacz & Butler, 2005; Wayne et al., 2004). This area of research has matured to the extent that two recent meta-analyses have appeared. Michel, Clark, and Jaramillo (2011) investigated the Big Five personality variables, negative work–family spillover (i.e., work–family conflict), and positive work–family spillover (i.e., work–family enhancement). Based on a meta-analytic structural equation model, extraversion, agreeableness, conscientiousness, and neuroticism were each significantly associated with negative work–nonwork spillover, with neuroticism demonstrating the strongest effect. Extraversion, agreeableness, conscientiousness, and openness to experience were each related to positive work–nonwork spillover, with extraversion demonstrating the strongest relationship.

Allen, Johnson, Saboe, Cho, Dumani, and Evans (2012) conducted a comprehensive meta-analysis of dispositional variables associated with WIF and FIW. The authors conclude that in general, negative trait-based variables (e.g., negative affect, neuroticism) appear to make individuals more vulnerable to both directions of work–family conflict, while positive trait-based variables (e.g., positive affect, self-efficacy) appear to protect individuals from work–family conflict. The largest effects reported were those associated with negative affect, neuroticism, and self-efficacy. These studies are an important contribution to the work–family literature in that the effect sizes associated with dispositional variables rival those associated with work–family stressors, and exceed those associated with work–family practice initiatives such as flextime.

Values

The role of individual life role values is an expanding area of research interest within the work–family literature. Life

role values pertain to what the individual believes to be important to, central to, or a priority in his or her life. Values are key to the choices individuals make with regard to work, family, and other pursuits (Perrewe & Hochwarter, 2001). Carlson and Kacmar (2000) found that sources, levels, and outcomes of work–family conflict differed depending on individual life role values. For example, when the family role was highly valued, work domain predictors were more highly associated with work–family conflict and satisfaction. A considerable number of studies have investigated values at the role domain level, such as family role salience (see Powell & Greenhaus, 2010, for a review); however, emerging research investigates values at a more fine-grained level.

Based on Schwartz's values theory (e.g., Schwartz, Melech, Lehmann, Burgess, & Harris, 2001), Cohen (2009) examined the link between 10 individual values and work–family conflict. Findings indicated a positive relationship between valuing power and both FIW and WIF. In addition, individuals who valued benevolence were more likely to report WIF while those who valued hedonism were less likely to report WIF. Notably, values that represent conservation (security, tradition, conformity) were not related to either direction of work–family conflict. Promislo, Deckop, Giacalone, and Jurkiewicz (2010) recently investigated the link between materialism, defined as placing a high value on income and material possessions (Diener & Seligman, 2004), and work–family conflict. Results after including a number of control variables indicated that more materialistic individuals also reported more FIW. Future research targeting issues of value similarity between family members and value congruence between the individual and the organization would be welcome extensions to this literature (Perrewe & Hochwarter, 2001).

Integration/Segmentation

One individual difference variable unique to the work–family literature is preferences for integration versus segmentation of work and family roles. Based on boundary theory, it is suggested that these preferences are developed by individuals in an attempt to manage work and family roles (Ashforth, Kreiner, & Fugate, 2000). Segmentation and integration are thought to reside at opposite ends of the same continuum (Kreiner, 2006). Individuals who fall more on the segmentation end prefer to keep work and family separate while those who fall more on the integration end prefer to remove boundaries and merge work and family roles. Effective boundary management is thought

to be important in that it facilitates performance in both the work and the family role (Ashforth et al., 2000; Edwards & Rothbard, 1999).

Investigations of the relationship between segmentation/integration preferences and work–family conflict have primarily yielded null results. To date, no significant relationship between segmentation/integration preferences and WIF has been detected (Kossek, Lautsch, & Eaton, 2006; Kreiner, 2006; Powell & Greenhaus, 2010; Shockley & Allen, 2010). Relationships with FIW have been nonsignificant (Shockley & Allen, 2010), or significant but small in magnitude, suggesting segmentation preferences associated with greater FIW (Kossek et al., 2006). Several studies suggest that *actual* segmentation of work and family roles is associated with less WIF (Olson-Buchanan & Boswell, 2006; Powell & Greenhaus, 2010). Powell and Greenhaus (2010) also found that actual segmentation was associated with less affective positive work-to-family spillover. Thus, the results thus far appear to suggest that preferences for segmentation/integration have little relationship to work–family conflict. However, actual segmentation of work and family roles may be beneficial in terms of preventing work–family conflict, but also inhibit positive spillover between roles.

Several studies have investigated the relationship between segmentation/integration preferences and use of flexible work arrangements. Kossek et al. (2006) found that integration preferences were associated with less telecommuting. In contrast, Shockley and Allen (2010) reported that integration preferences were associated with greater use of flextime and flexplace (also called *telecommuting*).

It seems likely that segmentation/integration may play a moderating role with regard to work–family relationships. For example, segmentation/integration may moderate the extent that work role stressors cross over to FIW and that family role stressors cross over to WIF such that those who tend to blur work and family role boundaries demonstrate stronger crossover relationships. This would be consistent with Rothbard, Philips, and Dumas (2005), who found that segmentation/integration preferences moderated relationships between the availability of workplace family supportive practices and job attitudes. This is in line with the notion that policies such as flexplace or telecommuting do not work equally well for everyone. For example, in a qualitative study, McDonald, Bradley, and Brown (2008) found that some individuals reported that they were too easily distracted to work from home while others reported that they were more productive when not physically present in the office.

Summary

Situational factors and to some extent demographic factors have been the primary predictors of interest within the work–family literature over the past several decades. The emerging focus on individual differences is an important complement to existing research. The strongest predictors appear to be variables associated with negative affect. However, much remains to be studied in terms of how dispositional variables might interact with each other as well as with situational variables to more fully explain work–family role experiences. In addition, further investigations of individual differences specific to work–family, such as integration/segmentation, are needed.

ENVIRONMENTAL SUPPORT FOR MANAGING WORK AND FAMILY

In this section, the literature regarding both organizational and legislative support for managing work and family is reviewed. The prevalence of various policies is noted as well as the research that supports their effectiveness.

Organizational Policies and Practices

Organizational policies and practices can be characterized as those that are formal or as those that are informal. Among the most commonly discussed formal practices are those involving dependent care and flexibility. Informal practices include supervisor support and organizational support. Each are reviewed below.

Dependent Care

There are a large number of policies that fall under the rubric of dependent care that range from referrals for elder care services to paid leave to care for sick family members. One source for information regarding the prevalence of these practices is the Society for Human Resource Management (SHRM), which conducts an annual study of the benefits offered by organizations. Their most recent report indicated that the most common dependent care–related benefit offered by companies was a dependent-care flexible spending account (72%) (SHRM, 2010). Additional data indicate that 24% of employers provide paid family leave, 19% provide paid leave above required federal FMLA leave, 17% provide parental leave above federal FMLA, and 16% provide paid adoption leave. Other dependent benefits include the ability to bring a child to work in an emergency (30%), on-site lactation/mother's

room (28%), child care referral service (17%), and elder care referral service (11%). Of the 23 family-friendly benefits assessed in the SHRM report, three decreased from 2006 to 2010 (elder care referral service, adoption assistance, and foster care assistance) and one increased (bring child to work in emergency). No changes in any of the offerings were detected between 2009 and 2010.

Research with regard to the impact of dependent care policies on employee outcomes is limited. Results can be divided into those that focus on use and those that focus on availability. With regard to use, the findings are mixed. Goff, Mount, and Jamison (1990) found no relationship between child care center use and employee absenteeism on work–family conflict. Kossek and Nichol (1992) reported that parents who used an employer-sponsored onsite child care center reported fewer child care problems and more positive work–family attitudes than did those who were on the waiting list; however, no relationship was detected with performance or employee absenteeism. Hammer, Neal, Newsom, Brockwood, and Colton (2005) reported that the use of dependent care supports (a variety of supports that included child and elder care) was *positively* associated with WIF for dual-career women.

With regard to availability, Grover and Crooker (1995) found that availability of child care was associated with attachment to the organization. Rothbard et al. (2005) report no relationship between perceived access to onsite child care and job satisfaction. However, this relationship was moderated by preferences for segmentation versus integration of work–family roles such that access to onsite child care was positively related to job satisfaction among those who preferred to integrate work and family roles and negatively related to job satisfaction among those who preferred to segment roles. A significant, but small-magnitude relationship was observed between perceived access to onsite child care and organizational commitment such that access was associated with less commitment. However, this relationship, too, was moderated by preferences for segmentation versus integration such that access to onsite child care was more negatively related to organizational commitment among those who preferred to keep life roles segmented than among those who preferred integration.

Mesmer-Magnus and Viswesvaran (2006) reported a meta-analytic effect size of -0.14 for WFC and -0.04 for WIF with dependent care availability and satisfaction. However, these effect sizes should be interpreted with caution because their research did not distinguish between child care arrangements provided by an employer versus

those provided by another source (e.g., homecare). This is an important distinction in that some individuals may prefer non-employer-related child care arrangements, particularly those who prefer to segment work and family roles.

Flexibility

A great deal of attention has focused on flexibility practices within organizations as a way to help individuals manage work and family responsibilities. Flexible work arrangements (FWA) are generally defined as work options that permit flexibility in terms of “where” work is completed (often referred to as *telecommuting* or *flexplace*) and/or “when” work is completed (often referred to as *flextime* or *scheduling flexibility*) (Rau & Hyland, 2002). Such practices have become widespread within organizations (SHRM, 2010). The great deal of attention focused on FWA has been fueled by the popular press (e.g., Greenhouse, 2011) and by policy advocates such as the *National Partnership for Women and Families* and *Corporate Voices for Working Families*. Moreover, in 2010 the White House held a forum on workplace flexibility (www.whitehouse.gov/blog/2010/04/01/a-conversation-workplace-flexibility) and the Women’s Bureau of the U.S. Department of Labor is engaged in a *National Dialogue on Workplace Flexibility* (www.dol.gov/wb/media/natdialogue2.htm).

The 2010 SHRM study reporting the percentage of employers offering various forms of flexibility indicated that the most commonly offered forms of flexibility were flextime (49%), telecommuting on an ad-hoc basis (44%), compressed work week (34%), and part-time telecommuting (34%). Less commonly offered were shift flexibility (19%), telecommuting on a full-time basis (17%), job sharing (13%), alternating location arrangements (4%), and results-only work environment (described below; 1%) (SHRM, 2010). The report also indicated no significant differences in flexible work benefits offered by employers between those surveyed in 2009 and in 2010. Some significant differences between 2006 and 2010 were reported. Specifically, there was a decline in the offering of flextime and an increase in the availability of telecommuting on a part-time basis. Thirteen other flexible work practices assessed showed no change. An additional source of information regarding the prevalence of flexibility practices is the *Work and Family Institute*. In their 2008 study it was reported that 79% of the organizations surveyed offered some degree of time flexibility, and 31% offered flextime on a daily basis (Galinsky, Bond, Sakai, Kim, & Giuntoli, 2008).

There is also evidence that employers intend to increase their flexibility offerings. In a 2010 survey of over 2,700 human resource professionals, 35% indicated that they planned to provide more flexible work arrangements to employees, compared to 31% surveyed in the previous year (CareerBuilder, 2010). In addition, a *Work and Family Institute* report found that most employers were either maintaining the flexible arrangements that they offer or planned to increase them (Galinsky & Bond, 2009).

Flexible work practices have been associated with a variety of beneficial work outcomes. Baltes, Briggs, Huff, Wright, and Neuman (1999) found that flexible workplace interventions were related to productivity, job satisfaction, work schedule satisfaction, and absenteeism in expected directions. Similarly, Gajendran and Harrison (2007) reported small but significant effects associated with telecommuting on work–family conflict, job satisfaction, performance, turnover intent, and role stress. One of the most progressive examples of flexibility is the “results-only work environment” (ROWE) at Best Buy (Conlon, 2006). At the Best Buy corporate office, employees are free to work where and whenever they want as long as the work gets done. In a study that compared employee turnover pre-ROWE and post-ROWE, Moen et al. (2011) reported that those in ROWE were less likely to leave the organization.

A great degree of practice and research attention has been focused on flexible work arrangements because they are thought to serve as a resource that enables individuals to better manage competing work and family demands. Although flexibility appears to have positive effects on job attitudes and behaviors, the evidence is far from unequivocal with regard to its relationship with work–family conflict (Allen & Shockley, 2009). Lapiere and Allen (2006) reported that telework users reported *more* time-based FIW than did non-users. No significant relationships were found between telework use and strain-based FIW, time-based WIF, or strain-based WIF. Based on both qualitative and quantitative data, Hill, Miller, Weiner, and Colihan (1998) examined those in a naturally occurring telecommuting situation (i.e., there was no self-selection) and those who worked in a traditional office space. With regard to work–life balance, participants wrote a total of 27 favorable (e.g., “Mobility enables me to better fulfill household/child care responsibilities”) and 46 unfavorable (e.g., “In the mobile environment I feel like I am always working”) qualitative comments. The quantitative analysis indicated that mobility was not significantly related to work–life balance. As these findings suggest, being able to work from home may enable negative work and

nonwork spillover rather than avert it. Along these lines, there is some evidence to suggest that the availability of flexibility in terms of scheduling is more effective for minimizing work–family conflict than is the availability of flexibility in terms of location (Shockley & Allen, 2007).

Given the cross-sectional design of most research relating flexibility and work–family conflict, one explanation for the aforementioned findings is that work–family conflict may motivate the use of flexible work practices (e.g., Allen & Shockley, 2009; Kossek et al., 2011). Although it seems unlikely that work–family conflict would increase the likelihood that one would report that flexible work options are available, experiencing work–family conflict may influence one to use flextime and/or to telecommute. This is important to keep in mind when interpreting existing findings and a factor to consider in the design of future research.

Supervisor Support

Supervisors have been recognized as essential to enabling employees to manage work and family. Research consistently indicates that individuals who report that their supervisors are more family supportive report less work–family conflict (e.g., Allen, 2001; Frone et al., 1997; Lapierre & Allen, 2006; Thomas & Ganster, 1995; Thompson, Beauvais, & Lyness, 1999). Moreover, family-supportive supervision has been associated with positive job attitudes, lower intentions to leave the organization, and more positive spillover from family to work (e.g., Allen, 2001; Hammer, Kossek, Yragui, Bodner, & Hanson, 2009). A similar line of research from a leadership perspective has documented that individuals who enjoy a high-quality leader–member exchange with their supervisors also report less work–family conflict (Bernas & Major, 2000; Golden, 2006; Major, Fletcher, Davis, & Germano, 2008).

Hammer and colleagues have recently conceptualized family-supportive supervision along four dimensions: emotional support, instrumental support, role modeling behaviors, and creative work–family management (Hammer et al., 2009). Emotional support involves making employees feel comfortable discussing work–family issues and conveying empathy. Instrumental support involves effectively responding to employee work and family needs and requests. Role modeling behaviors refer to the supervisor’s ability to demonstrate effective strategies for effective work–family management. Creative work–family management is defined as manager-initiated behaviors intended to restructure work in a way that facilitates employee effectiveness on and off the job. Each

of these four dimensions was associated with less WIF and more positive family–work spillover. In addition, role modeling was associated with positive work–family spillover.

Given the benefits associated with family-supportive supervision, it is not surprising that researchers would turn their attention to ways to increase such support. The effectiveness of an intervention designed to train supervisors to be more family-supportive was recently tested, with somewhat mixed results (Hammer, Kossek, Anger, Bodner, & Zimmerman, 2011). For example, while the training was successful at improving work and health outcomes for employees with higher levels of FIW, the intervention had detrimental effects for employees with lower levels of FIW. The inclusion of additional intervention studies is a critical need within the work–family literature.

Informal Organizational Support

Informal aspects of the workplace environment also play a role in the work–family interface. An assortment of constructs with similar content have been developed that capture an overall assessment of the family-supportiveness of the organization. They include work–family culture (Thompson et al., 1999), family-supportive organizational perceptions (FSOP) (Allen, 2001), face-time orientation (Shockley & Allen, 2010), and work–family climate (Kossek, Colquitt, & Noe, 2001; O’Neill, Harrison, Cleveland, Almeida, Stawski, & Crouter, 2009). What these constructs have in common is the recognition that norms and expectations within the organization influence the extent that employees feel comfortable using policies such as flextime, can talk openly with regard to work–family concerns, and feel compelled to place work ahead of family. Perceiving that the organization is more family-supportive relates to a variety of positive outcomes that include less work–family conflict, greater job satisfaction, less intention to quit, and greater employee well-being (e.g., Allen, 2001). Moreover, the effect sizes associated with informal support tend to be considerably stronger than those associated with specific organizational practices such as schedule flexibility (Anderson, Coffey, & Byerly, 2002; Michel et al., 2011).

Legislative Policy

Policies at the national level that are supportive of employee needs to manage work and family responsibilities have increasingly become a topic of discourse within the work–family literature. It is widely recognized that legislative policies or government-level supports for work

and family vary enormously across the world (Heymann, Earle, & Hayes, 2007; Waldfogel, 2001). Countries differ in terms of the extent that paid leave for childbirth and adoption is provided, paid leave for sickness is available, child care is readily available and affordable, and that early education programs exist (Heymann et al., 2007; Human Rights Watch, 2011).

Legislative policy at the national level within the United States with regard to paid work–family supports is limited. The United States has no federal guaranteed paid leave for mothers for childbirth or adoption. In contrast, Heymann et al. (2007) reported that 169 of the 173 countries they studied offered guaranteed leave with income to women in connection with childbirth and 98 of those countries offer 14 or more weeks of paid leave. Unpaid leave is mandated within the United States. The Family and Medical Leave Act (FMLA), signed in 1993, guarantees eligible employees 12 weeks of unpaid job-protected leave during any 12-month period for an employee’s serious medical condition, childbirth, adoption, foster care placement, or to care for a spouse, parent, or child. Employees are eligible if they have worked at least 1,250 hours during the preceding year. However, employers who have fewer than 50 employees within a 75-mile radius of all worksites are exempt.

States are beginning to implement their own paid family leave law. California was the first to do so in 2002 (Milkman & Appelbaum, 2004). In California, workers who participate in the State Disability Insurance Program are eligible for up to 6 weeks of partial pay each year for bonding with a newborn/adopted child or to care for an ill family member. In 2009, a similar law went into effect in New Jersey. Washington approved a law intended to provide up to 5 weeks of paid family leave associated with the birth or adoption of a child in 2007. However, due to a state budget deficit, implementation has been postponed until 2012 (Washington, Family Leave Coalition, n.d.).

Other forms of family-related entitlements strikingly differ across countries. In the United States, parents rely on tax credits to help with child care expenses, whereas child care assistance in Europe is often provided through publicly funded programs (Waldfogel, 2001). Unlike other industrialized countries, the United States has no federally mandated paid sick leave or vacation leave. Paid sick leave and vacation are left at the discretion of the employer. In recent years, there have been growing efforts by policy advocates to implement a mandated paid sick leave policy. For example, the *Healthy Families Act*, introduced into Congress, would require employers who employ 15 or

more employees for each working day 20 or more work-weeks a year to provide employees up to 7 paid sick days per year (Heymann, 2007).

The common assumption is that these policies are important for managing work and family conflict. Williams (2010) asserts, “Failures of public policy are a key reason that Americans face such acute work–family conflict” (p. 8). However, this assumption has been subjected to little empirical scrutiny. In fact, several studies appear to suggest that national policy has little impact on the day-to-day working lives of employees. For example, Strandh and Nordenmark (2006) investigated work–family conflict in five countries (Sweden, the Netherlands, the United Kingdom, Hungary, and the Czech Republic) that differed in terms of the extensiveness that governmental supports exist. They hypothesized that individuals living in countries with more generous country-level social supports (i.e., Sweden) would experience less work–family conflict than would individuals living in countries with less generous social supports (i.e., the United Kingdom). However, the results contradicted their hypothesis in that women in Sweden reported more conflicts between work and household demands than did any other category across all five countries. Similarly, a recent qualitative study revealed that women in the United Kingdom and the Netherlands reported that national policy had not impacted their lives in any tangible way (Yerkes, Standing, Wattis, & Wain, 2010).

Summary

There is still much to be understood with regard to the types of supports that are most beneficial to individuals struggling with the challenge of balancing work and family. To date, the existing research suggests that informal supports at the local level may be most effective. Most research investigating family supportive organizational perceptions/culture has investigated it as a predictor variable. Research aimed at identifying the factors that feed into perceptions of family supportiveness as well as objectively identified forms of family-supportive cultures is needed.

CROSS-NATIONAL WORK AND FAMILY RESEARCH

Work–family scholarship has flourished not only in the United States, but also in other countries across the globe (Allen, Shockley, & Biga, 2010; Poelmans, 2005). Despite

the widespread interest in work and family globally, cross-national comparative studies remain relatively rare. Two points of comparison are of interest. One is the prevalence of work–family conflict. The second is generalizability of relationships involving the work–family interface cross-nationally. The literature regarding each of these is reviewed below.

Cross-National Prevalence of Work–Family Conflict

Gauging the prevalence of work–family conflict across countries is difficult in that no representative sampling studies have been conducted. Moreover, we have no way to ensure that work–family conflict has the same conceptual meaning in the United States as it does in countries outside of the United States. Despite these limitations, a handful of studies do exist that begin to provide some insight into comparative levels. Spector, Allen, Poelmans, Cooper et al. (2005) investigated pressures emanating from work that spilled over into the family among a sample of managers from 18 countries. They found that individuals from Taiwan, Hong Kong, and Portugal reported the greatest work–family pressure while individuals from the United States, the United Kingdom, and Australia reported the least. As previously described, Strandh and Nordenmark (2006) investigated work–family conflict in five countries grouped under different social contexts. Individuals residing in Sweden reported the greatest degree of work–family conflict, followed by those in the Netherlands, the UK, Czech Republic, and lastly Hungary. In a three-country comparison study, Mortazavi, Pedhiwala, Shafiro, and Hammer (2009) found no mean differences in WIF or FIW across the United States, Ukraine, and Iran. Yang (2005) found that WIF was greater in China than in the United States, but no significant mean difference in FIW was detected. In both of the two aforementioned studies it is notable that, similar to research based primarily in the United States, participants in all country samples reported more WIF than FIW.

Research has also been conducted investigating work–family conflict across country clusters. Spector et al. (2007) grouped 5,270 managers from 20 countries into four clusters: Anglo, Asian, East-European, and Latin American. Both time- and strain-based WIF were investigated. The means associated with the Anglo and the Asian clusters significantly differed such that individuals in the Anglo cluster reported the highest time-based WIF. In addition, the strain-based Asian cluster mean was significantly lower than that of any of the other three clusters.

Another way to compare prevalence is based on country clusters created according to cultural values. Cultural values have been defined as “shared motives, values, beliefs, identities, and interpretations or meanings of significant events that result from common experiences of members of collectives that are transmitted over generations” (House & Javidan, 2004, p. 15).

Based on data from over 20,000 managers across 50 countries employed by a large multinational firm, Allen et al. (2010) investigated mean differences in work–life effectiveness (i.e., the absence of WIF) based on groupings of countries clustered into high, medium, and low bands with regard to the cultural values of gender egalitarianism, collectivism, humane orientation, and performance orientation. Interesting differences emerged. Individuals in medium gender egalitarian (GE) societies reported the greatest work–life effectiveness, followed by those in high GE societies. The lowest work–life effectiveness was in low GE societies. Work–life effectiveness also followed a nonlinear trend with regard to humane orientation. The greatest work–life effectiveness was reported among managers in the medium-high humane orientation cluster. A linear trend was found with collectivism such that greater work–life effectiveness was associated with lower collectivistic values. Stronger performance orientation was associated with greater work–life effectiveness.

Based on the literature accumulated thus far, conclusions regarding differences in prevalence rates across countries and cultures are difficult to draw. Adding to the complexity is that there is a great degree of variation in the sampling strategies used in the studies to date, making meaningful comparisons risky. However, it does seem safe to tentatively conclude that contrary to what has been suggested by some scholars (e.g., Williams, 2010), individuals in the United States do not necessarily report the highest degree of work–family conflict across the globe.

Generalizability of Work–Family Relationships

The majority of early work and family research was conducted within the United States and other Western countries (Poelmans, 2005). In recent years, a growing number of studies have examined the generalizability of findings conducted within a Western context to other contexts. Much of this research has been based on identifying unique relationships theorized to be due to cultural differences in collectivism (e.g., Spector et al., 2004, 2007; Yang, 2005; Yang, Chen, Choi, & Zou, 2000). The

general finding is that relations between work–family conflict and predictors and between work–family conflict and outcomes are weaker in more collectivistic than in less collectivistic societies. These findings are attributed to the notion that in more collectivistic societies work is viewed as something done for the family while in less collectivistic societies work is viewed as something done for the self.

Other research has found that work–family relationships are invariant across multiple country contexts. Hill, Yang, Hawkins, and Ferris (2004) demonstrated that a model that linked work demands to WIF held universally across four country clusters based on 48 countries. Likewise, Mortazavi et al. (2009) reported that work demands were associated with WIF across three countries. Based on data from five individualistic countries, Lapierre et al. (2008) tested a model that linked family-supportive organizational perceptions to both directions of work–family conflict, which was in turn linked to job satisfaction and family satisfaction. The model was generalizable across all five countries. Lallukka et al. (2010) investigated relationships between a bidirectional assessment of work–family conflict and health behaviors across samples of British, Finnish, and Japanese employees. Similar relationships were found across the three cohorts.

Several studies have investigated issues associated with workplace flexibility and culture. Raghuram, London, and Larsen (2001) examined the amount of variance accounted for in telework use by culture versus country. The authors concluded that differences in use were explained by country differences rather than by culture differences. Masuda et al. (2012) investigated the relationship between the availability of an assortment of flexible work arrangements and WIF across Latin American, Anglo, and Asian country clusters. Significant differences in relationships were found. Specifically, flextime was the only form of flexibility that had significant favorable relationships with the outcome variables among managers in the Anglo cluster. With regard to managers in the Latin American cluster, part-time work negatively related with turnover intention and strain-based WIF. For Asians, flextime was unrelated with time-based WIF, and telecommuting was positively associated with strain-based WIF. Finally, Allen et al. (2010) found variability in the relationships between flexibility and work–life effectiveness across cultures. Their overall pattern of results suggested that the availability of flextime could potentially help compensate for cultural contexts that may make the achievement of work–life effectiveness more difficult.

Summary

A small, but growing body of cross-national work and family research has begun to accumulate in recent years. To date the focus has been on work–family conflict with findings suggesting that many of the same predictors and outcomes may generalize across various national contexts but that the strengths of these relationships differ. Much of this research has been geared toward comparing results found in non-Western contexts to those found in the West. The development of emic as well as etic approaches could yield a clearer understanding of how individuals from various cultural contexts experience combining work and family. Opportunities for future research also include investigating the positive aspects of combining work and family roles.

FUTURE RESEARCH DIRECTIONS

As mentioned at the beginning of this chapter, work and family scholarship has grown tremendously in the past several decades. Although a substantial body of research has developed, many areas for further inquiry remain. Three high-priority directions are suggested in the following sections.

Technology/Virtual Work

Advanced technology has changed the way work is done as well as where it can be done. Profound changes continue to occur with regard to the ways people work with virtual workspaces and the potential for constant connection to work. The “workplace” can no longer be solely linked with a discrete physical location (Kreiner, Hollensbe, & Sheep., 2009). These advancements have the potential to both help and harm individuals in terms of the effective management of work and family roles.

On one hand, the constant connection to both work and home can blur the boundary between work and non-work and therefore increase vulnerability to work–family conflict (Boswell & Olson-Buchanan, 2007). About half (49%) of employees report that the use of technological tools increases their stress and makes it difficult to separate work and nonwork responsibilities (Madden & Jones, 2008). Another by-product of the increased ability of employees to work from home appears to be an increase in the total number of hours worked (Fenner & Renn, 2010). On the other hand, the availability of communication technology can empower employees to

work where and when they believe they can be most effective. In addition, technology facilitates the ability to engage in cross-role communication. For example, parents can use smartphones to quickly check in on and send reminders to their children via text messages while at work (St. George, 2009).

Given both the advantages and pitfalls associated with technology, research is needed that further explores the ways in which the positive power of technology best can be harnessed. One possibility is providing individuals with time management skills. Fenner and Renn (2010) investigated the link between technology-assisted supplemental work (TASW) and WIF. They found a positive relationship between greater use of TASW and greater WIF; however, time management moderated the relationship. Specifically, the relationship between TASW and WIF was stronger when individuals had low goal setting and priority skills. This is consistent with research that has shown that a negative relationship between control at work and WIF is observed only among employees who use a high degree of planning behavior (Lapierre & Allen, *in press*). That is, planning behavior is important for being able to realize positive benefits from control. Thus, providing individuals with the ability to control when and where they work through technology may not have intended beneficial effects without being accompanied with appropriate time management skills.

Another skill that needs further investigation is the setting of appropriate boundaries with regard to technology use. Olson-Buchanan and Boswell (2006) found that employees who set fewer boundaries for the use of communication during nonwork time also reported greater WIF. Similarly, Boswell and Olson-Buchanan (2007) reported that the use of communication technologies after normal work hours related to WIF. Along these lines, Turkle (2011) describes how the teenagers she interviewed complain that their parents are immersed with their phones during dinner, sporting events, and when picking them up from school. Parents recognize the behavior, but rationalize it on the basis of feeling ever behind, trying to keep up with e-mail and other messages. Further research on the development of boundary-related policies and their impact is needed.

Finally, research is needed that investigates the overuse and extended use of communication technologies on both work and family-related outcomes. Turkle (2011) describes how technology permits us to do anything from anywhere with anyone, but also drains us as we try to do everything everywhere. She suggests that networked devices encourage a new notion of time because they permit the layering of more activities onto one another. For

example, because one can text while also doing something else, an illusion is created that texting does not take time but gives time. The abundance of communication technology can result in individuals becoming so busy communicating that little time is left for real work or for real relationships. She suggests that the long periods of time without distractions and interruptions needed to do productive work and to maintain quality relationships have waned. To better understand these issues, we need to tease apart voluntary and involuntary use of technology as well as voluntary and involuntary distractions.

Connecting Work–Family Research with Neuroscience

The study of work and family is multidisciplinary in scope, with contributions from researchers across a variety of disciplines (Pitt-Catsouphes, Kossek, & Sweet, 2005). Although most work–family research has drawn primarily from social science perspectives, biological perspectives have also increased our understanding of work–family interactions. For example, work and family demands have been associated with elevated blood pressure (Brisson, Laflamme, & Moisan, 1999) and elevated norepinephrine (Lundberg & Frankenhaeuser, 1999). However, work–family research has yet to incorporate neuroscience.

In several recent articles, Becker and Cropanzano have proposed the development of *Organizational Neuroscience* (Becker & Cropanzano, 2010; Becker, Cropanzano, & Sanfey, 2011). They define organizational neuroscience as “a deliberate and judicious approach to spanning the divide between neuroscience and organizational science” (p. 1055; see also Becker & Cropanzano, 2010) and encourage organizational scholars to consider a neuroscientific perspective in their work. Such a perspective could be helpful toward the advancement of work–family research.

Neuroscience can provide insight into the processes involved in the regulation of multiple role demands (Allen, 2012). The function of the prefrontal cortex (PFC) is to regulate behavior, attention, and affect (Brennan & Arnsten, 2008). It plays a key role in the planning system, facilitating the successful formulation of goal-directed behavior (Becker & Cropanzano, 2010). The amygdala within the brain is involved in the assessment of threat-related stimuli and the processing of emotional reactions (Shin, Rauch, & Pitman, 2006). When a stressful event is encountered (e.g., a work–family dilemma), the amygdala induces catecholamine release in the

prefrontal cortex, which results in cognitive dysfunction. Inhibition of the PFC weakens the ability to multitask (Diamond, Campbell, Park, Halonen, & Zoladz, 2007). Extreme examples of such failures include caregivers who forget that a child is in the car. Neuroscientists attribute such events to a breakdown in the brain's memory circuit due to a combination of stress and emotion, often accompanied by a lack of sleep and a change in routine (Weingarten, 2009). Research that investigates the brain's response to stressors that involve work–family conflicts and demands may help produce recommendations for alleviating work–family-related strain.

One specific topic for research is mindfulness. Mindfulness has been defined as “intentionally paying attention to present-moment experience (physical sensations, perceptions, affective states, thoughts, and imagery) in a nonjudgmental way, thereby cultivating a stable and nonreactive awareness” (Carmody, Reed, Kristellar, & Merriam, 2008). Dispositional mindfulness has been negatively associated with psychological distress, rumination, and social anxiety while positively correlated with clarity of emotional states, mood repair, and relationship satisfaction (e.g., Carmody et al., 2008; Chambers, Lo, & Allen, 2008). Mindful regulation of behavior is energizing (Brown & Ryan, 2003), while self-controlled regulation of behavior is energy depleting (e.g., Baumeister, Bratslavsky, Muraven, & Tice, 1998). Mindful regulation of behavior differs from self-controlled regulation of behavior in that the practice of mindfulness has been found to strengthen rather than inhibit working memory (Jha, Stanley, & Baime, 2010).

Indeed, the therapeutic effects of mindfulness have been attributed to changes in the brain. Specifically, verbally labeling affective stimuli activates the right ventrolateral PFC and reduces responses in the amygdala (Cresswell, Way, Eisenberger, & Lieberman, 2007). Thus, mindfulness is associated with enhancements in neural affect regulation pathways.

One study has found a relationship between dispositional mindfulness and work–family conflict such that more mindful individuals report less work–family conflict (Kiburz & Allen, 2011). Thus, the cultivation of mindfulness processes through training may be one tool that can help regulate affect and alleviate perceived work–family conflict.

One final topic in this area ripe for research is implicit processes. The distinction between implicit and explicit attitudes has been a recent topic of interest within I-O psychology (e.g., Johnson & Lord, 2010). Implicit processes as compared to explicit processes occur more

automatically, take place in the deep brain structures of the temporal lobe, and are less likely to be within the conscious awareness of the individual (Becker et al., 2011).

Research investigating implicit processes could elucidate issues related to gender, parenthood, and differential work–family outcomes. In a study of implicit and explicit processes, Park, Smith, and Correll (2010) reported that the concepts of mom and parent were more easily kept simultaneously in mind than were mom and professional. The opposite effect was found for dad. For the category female, the mom role was more readily activated than was the dad role for male. Men were more strongly associated with the professional work role while women were more strongly associated with the home role. Implicit assumptions were associated with recommendations for how to best deal with work–family conflict such that those with the strongest traditional implicit role associations were more likely to recommend solutions that had women putting family first and men putting work first. These findings may explain why the behavioral expectations with regard to men and women have been difficult to change. Because implicit and explicit attitudes develop from different parts of the brain, implicit attitudes take priority. They therefore can short-circuit subsequent beneficial cognitive processing (Becker et al., 2011). Additional research exploring the implicit attitudes held with regard to career, family, and gender could help further reveal biases associated with both men and women. For example, studies could be done investigating implicit associations within the context of the distribution of family labor, use of flexible work options, and care of dependent family members.

Older Workers

Much attention has been given to the aging workforce (Hedge, Borman, & Lammlein, 2005). Despite the fact that engagement in work and family roles occurs throughout the life span, there has been relatively little focus on work and family issues among older workers. As noted by Allen and Shockley (2012), there are multiple reasons to consider older workers from a work–family perspective. The age of women with young children has increased as women have delayed the age of first childbirth and continue to bear children into the 40s in greater numbers. In addition, there are increasing numbers of grandparents as primary caregivers and employed workers with elder care responsibilities. Moreover, recent research indicates that 57% of individuals working and caring for elderly

parents report difficulty coping with both (Gautun & Hagen, 2010).

There are several topics in need of investigation. There have been few studies of work–family conflict or work–family enhancement at different ages. Although there is some evidence that work–family conflict declines with age (Gordon, Litchfield & Whelan-Berry, 2003), we need a richer understanding of how work–family issues may qualitatively differ at various points across the life span. Different issues may come into play at older ages that are not reflected in our standard work–family assessments. The demands associated with caring for grandchildren can be unique in that such arrangements are often prompted by a family crisis such as teen pregnancy, incarceration, and substance abuse (e.g., Wang & Marcotte, 2007). In addition, although mean levels of work–family conflict may decline, it may be that relationships with outcomes differ. That is, age may act as a moderator. For example, the relationship between work–family conflict and depression may be stronger for older workers caring for aging parents than for younger workers caring for children. Finally, assessment of positive interactions between work and family as individuals age are needed.

The application of a life course perspective to research on older workers would be ideal to address questions such as how decisions made in early life with regard to the balance between work and family impact decisions regarding work and family dilemmas later in life. For example, decisions made by women over the life course to favor the spouse's career, take time off for childbearing, and reduce work effort in favor of dependent caregiving, can have later economic disadvantages for women such as reduced pensions (Allen & Shockley, 2012; Pavalko & Gong, 2005). The impact of these decisions on later quality of life and well-being have yet to be fully investigated.

A final topic to consider with regard to older workers is research at the family unit of analysis. The work–family literature is generally in need of research at levels other than the individual (Allen, 2012). Research investigating family and work networks based on social network analysis may be especially useful in understanding how lives are linked across the life span. Studies are needed to understand how these networks contribute to resilience in the face of declining health, coping with involuntary job loss, and the decision to retire (Fry & Keyes, 2010).

CONCLUSIONS

The objective of this chapter has been to expose the reader to the major themes within the work–family literature

as well as to emerging topics of interest. Industrial and organizational psychologists have been responsible for generating many insights into the work–family interface over the past several decades. Continued advancements will require innovative research designs and boundary-spanning ideas that chart new paths. As families and organizations continue to change, I-O psychologists can continue to play an important role in producing research findings with the potential to benefit both individuals and organizations.
